Holists challenge this consensus by first arguing that caricatured formulations of holism that ignore human action must be set aside. They then ask us to re-examine the nature of human action. Action is distinguished from mere behaviour by its intentional character. This much is uncontested between individualists and holists. But against the individualist contention that intentions exist as only psychological states in the heads of individuals, the holist argues that they also lie directly embedded in irreducible social practices, and that the identification of any intention is impossible without examining the social context within which agents think and act. Holists find nothing wrong with the need to unravel the motivations of individuals, but they contend that these motivations cannot be individuated without appeal to the wider beliefs and practices of the community. For instance, the acquiescence of oppressed workers may take the form not of total submission but subtle negotiation that yields them sub-optimal benefits. Insensitivity to social context may blind us to this. Besides, it is not a matter of individual beliefs and preferences that this strategy is adopted. That decisions are taken by subtle strategies of negotiation rather than by explicit bargaining, deployment of force or use of high moral principles is a matter of social practice irreducible to the conscious action of individuals.

Two conclusions follow if the holist claim is true. First, that a reference to a social entity is inescapable even when social facts are explained in terms of individual actions, because of the necessary presence of a social ingredient in all individual intentions and actions. Second, a reference to individual actions is not even necessary when social facts are explained or understood in terms of social practices. Thus, the individualist view that explanation in social science must rely wholly and exhaustively on individual entities is hotly contested and is not as uncontroversial or trivial as it appears.

HOLISM: MENTAL AND SEMANTIC

Mental (or semantic) holism is the doctrine that the identity of a belief content (or the meaning of a sentence that expresses it) is determined by its place in the web of beliefs or sentences comprising a whole theory or group of theories. It can be contrasted with two other views: atomism and molecularism. Molecularism characterizes meaning and content in terms of relatively *small parts* of the web in a way that allows many different theories to share those parts. For example, the meaning of 'chase' might be said by a molecularist to be 'try to catch'. Atomism characterizes meaning and content in terms of *none* of the web; it says that sentences and beliefs have meaning or content independently of their relations to other sentences or beliefs.

One major motivation for holism has come from reflections on the natures of confirmation and learning. As Quine observed, claims about the world are confirmed not individually but only in conjunction with theories of which they are a part. And, typically, one cannot come to understand scientific claims without understanding a significant chunk of the theory of which they are a part. For example, in learning the Newtonian concepts of 'force', 'mass', 'kinetic energy' and 'momentum', one does not learn any definitions of these terms in terms that are understood beforehand, for there are no such definitions. Rather, these theoretical terms are all learned together in conjunction with procedures for solving problems.

The major problem with holism is that it threatens to make generalization in psychology virtually impossible. If the content of any state depends on all others, it would be extremely unlikely that any two believers would ever share a state with the same content. Moreover, holism would appear to conflict with our ordinary conception of reasoning. What sentences one accepts influences what one infers. If I accept a sentence and then later reject it, I thereby change the

inferential role of that sentence, so the meaning of what I accept would not be the same as the meaning of what I later reject. But then it would be difficult to understand on this view how one could rationally – or even irrationally! – change one's mind. And agreement and translation are also problematic for much the same reason. Holists have responded (1) by proposing that we should think not in terms of 'same/different' meaning but in terms of a gradient of similarity of meaning, (2) by proposing 'two-factor' theories, or (3) by simply accepting the consequence that there is no real difference between changing meanings and changing beliefs.

NED BLOCK

HOLOCAUST, THE

The specific, tragic event of the Holocaust – the mass murder of Jews by the Nazis during the Second World War – raises profound theological and philosophical problems, particularly problems about the existence of God and the meaning of Jewish existence. Among the thinkers who have tried to wrestle with the conceptual challenge posed by the destruction of European Jewry, three who have presented original arguments that can be termed, in a relatively strict sense, philosophical are Richard L. Rubenstein, Emil Fackenheim and Arthur A. Cohen.

Rubenstein has formulated an argument that turns on the theological difficulties raised by the realities of the evil of Auschwitz and Treblinka in a world putatively created and ordered by a benign God. For him, such evil decisively refutes the traditional theological claim that a God possessed of goodness and power exists, and entails the conclusion that 'there is no [traditional] God'. In working out this conceptual position, he uses an unsatisfactory empirical theory of verification concerning religious propositions and too narrow a notion of evidence, both historical and ethical, that ultimately undermines his counterclaims and 'Death of God' affirmations.

Fackenheim seeks not to defend a religious 'explanation' of the Holocaust, but rather to provide a 'response' to it that maintains the reality of God and his continued presence in human, and particularly Jewish, history. To do so, he uses Martin Buber's understanding of dialogical revelation, asserting that revelation is an ever-present possibility, and formulates his own moral-theological demand to the effect that after the Holocaust, Jewish survival is the '614th commandment' (there are 613 commandments in classical Judaism). Fackenheim's defence of this position, however, is philosophically problematic.

Cohen provides a 'process theology' argument as an explanation of the Holocaust; that is, the Holocaust requires a revision in our understanding of God's nature and action. It forces the theological conclusion that God does not possess the traditional 'omni' predicates; God does not intervene in human affairs in the manner taught by traditional Western theology. However, Cohen's working out of a process theological position in relation to the Holocaust raises as many philosophical problems as it solves.

STEVEN T. KATZ

HOOKER, RICHARD (1554–1600)

Hooker's *Of the Laws of Ecclesiastical Polity* (1593–1662) is the first major work of English prose in the fields of philosophy, theology and political theory. After setting out an entire worldview in terms of the single idea of law, Hooker attempted to justify – and, arguably, to transform – the religious and political institutions of his day. Hooker's work contributed to later, more narrowly political, political thought (Locke cited 'the judicious Hooker' at crucial points in his *Second Treatise of Civil Government*), but the *Laws* is chiefly significant for articulating the ideal of a society coherent in and through its religion, a body politic which succeeds in being – not merely having – a church. In Hooker's England this meant that royal authority in religion was extensive, but derived from the community and limited by law. Modern separations of politics from religion and of philosophy from edification have made him difficult to assimilate. More recent critiques of Enlightenment secularism and purely technical philosophy help make him again intelligible.

HUMAN NATURE

Introduction

Every political philosophy takes for granted a view of human nature, and every view of human nature is controversial. Political philosophers have responded to this conundrum in a variety of ways. Some have

defended particular views of human nature, while others have sought to develop political philosophies that are compatible with many different views of human nature, or, alternatively, which rest on as few controversial assumptions about human nature as possible. Some political philosophers have taken the view that human nature is an immutable given, others that it is shaped (in varying degrees) by culture and circumstance. Differences about the basic attitudes of human beings toward one another – whether selfish, altruistic or some combination – have also exercised political philosophers. Although none of these questions has been settled definitively, various advances have been made in thinking systematically about them.

Four prominent debates concern: (1) the differences between *perfectionist* views, in which human nature is seen as malleable, and *constraining* views, in which it is not; (2) the *nature/nurture* controversy, which revolves around the degree to which human nature is a consequence of biology as opposed to social influence, and the implications of this question for political philosophy; (3) the opposition between *self-referential* and *other-referential* conceptions of human nature and motivation – whether we are more affected by our own condition considered in itself, or by comparisons between our own condition and that of others; and (4) attempts to detach philosophical thought about political association from all controversial assumptions about human nature.

1 Perfectionist versus constraining views of human nature

The most celebrated proponent of perfectionist views of human nature is Aristotle, and his most elaborate discussion of the question appears in *The Nicomachean Ethics* (*c*.330 BC). Aristotle's view developed there is sometimes described as teleological because it was defined by reference to a fundamental contrast between untutored or brute human nature on the one hand, and human nature as it could be if we realized our essential nature or Telos on the other (see Telos). Ethics, for Aristotle, is the science that instructs us how to get from the one to the other. When correctly employed, ethical precepts thus have the potential to transform human beings from their rude and untutored states into the best kinds of beings they can become.

Although there is both room and need for human nature to develop and change on Aristotle's view, his is a *naturalist* one in that both the accounts of brute human nature and perfected human nature are rooted in a philosophical psychology, a theory of natural human needs and potentials. Naturalist views are generally distinguished from *anti-naturalist* accounts, in which the sources of meaning and value for human beings are externally given, whether in Platonic forms, transcendental arguments about the nature of knowledge and obligation, or some other extrinsic origin. On anti-naturalist views what is good or right is good or right regardless of actual human needs and desires, whereas for naturalists the gulf between 'is' and 'ought' is bridged via an account of human needs or psychology (see Naturalism in ethics). Naturalist perfectionism can be secular or theologically-based; indeed, much medieval Christian Aristotelianism rested on the adaptation of the story of the Garden of Eden, the Fall from Grace, and the possibility of redemption to Aristotle's ethical categories. Marxism, on the other hand, is a secular version of naturalist perfectionism. For Marx, human beings as we find them are alienated from their 'true' selves, their potential stunted by a variety of malevolent forces. But these forces are in some sense artificial impediments to human flourishing that can be understood and ultimately vanquished, opening the way for authentic human development (see Alienation).

Although perfectionist views can be naturalist or anti-naturalist, constraining views of human nature are invariably naturalist in character. Proponents of constraining views regard human nature as an immutable given, holding that social and political institutions must take account of it but have no effect on it. Perhaps the most extreme proponent of this view in the history of Western philosophy was Jeremy Bentham, who made it an axiom of his utilitarian system that nature: 'has placed mankind under the governance of two sovereign masters, *pain* and *pleasure*' (1948: 125). For Bentham, pleasure seeking and pain avoidance 'govern us in all we do, in all we say, in all we think: every effort we can make to throw off our subjection, will serve but to demonstrate and confirm it' (1948: 125). Bentham believed that the utilitarian system he advocated was uniquely scientific in that it recognized our inescapable subjection to the pleasure/pain calculus.

Although Bentham offers one of the most forthright and clear accounts of a constraining view of human nature, his is by no means the first or the only such view in the history of Western political theory. In their modern form such views

are traceable at least to Hobbes' insistence, *contra* Aristotle, that human nature is rigidly fixed. For Hobbes (1651) human beings are inescapably driven by a primordial fear of death, which produces in them a 'relentless desire for power after power'. Basic human impulses can be channelled in more and less productive ways, and to some extent people can be educated to see that certain political allegiances are better than others given their basic impulses, but the impulses themselves cannot be altered (see HOBBES, T. §6).

Utilitarians since Bentham have generally regarded human nature as given and external to the operations of political and cultural institutions. Even if utilitarians have differed greatly from one another concerning the content of human nature and even how much we can reasonably aspire to know about its content, they have generally accepted Hume's dictum that 'reason is the slave of the passions'. Whereas Hume, like Bentham, thought we are all driven by the same passions in the same ways, neoclassical utilitarians of the late nineteenth and early twentieth centuries (such as Pareto) questioned this assumption, taking a view of human nature that was perhaps most decisively stated by the emotivist philosopher Charles Stevenson in his critique of Hume: that even if we are convinced that all human beings are driven by needs for gratification of some sort, there is no decisive reason to think we all have the same such needs, or even that we can intelligently compare different desires experienced by different individuals with one another. This is the standard view in modern economics and rational choice theories of politics. Preferences are thought of as exogenously determined, but the possibility of meaningful interpersonal comparisons of preferences across individuals is denied (see UTILITARIANISM; ECONOMICS AND ETHICS).

2 The nature/nurture controversy

Since time immemorial scientists and philosophers have debated the question whether human nature is biologically given or rather the result of contingencies of cultural and historical circumstance, and these debates have been thought to be pregnant with political significance. ROUSSEAU (§2), for example, was the first in a long line of political theorists who have argued that Hobbes' political system was based on a confusion of parochial traits that were the product of seventeenth-century English life with enduring features of the human condition. In Rousseau's view, Hobbes wrongly thought the impulse toward self-preservation was incompatible with a desire to preserve others: 'because of [his] having improperly included in the savage man's care of self-preservation the need to satisfy a multitude of passions which are the product of society' (*The First and Second Discourses*). Rousseau's own account of the state of nature has been criticized on analogous grounds however. Indeed it has become a standard move in modern political argument to question every assertion about natural human traits and propensities, however qualified or historicized, by arguing that the traits in question are socially produced or 'socially constructed'. Such debates can become exceedingly heated when they become embroiled in discussions of the determinants of intelligence and such things as ethnic, racial and gender differences (see SOCIOBIOLOGY).

The nature/nurture controversy is often confused with the issue of whether or not human nature is alterable by human design. It is often said, for instance, that much or all of human nature is socially constructed rather than naturally given, and that for this reason it should not be regarded as immutable. In fact, whether a given human characteristic is a product of nature or culture may have little to do with the degree to which it is alterable by conscious human design. On the one hand, there are many features of the natural world that human beings have effectively altered and will alter more in the future; the science of genetic engineering, for example, is presumably in its infancy. On the other hand, there are many pieces of human reality that, while indisputably the product of human action, we often seem powerless to influence. Ethnic hatred may be learned, for example, yet it may be impossible to get people to unlearn it or even to stop them passing it on to the next generation.

It is sometimes thought that cultural creations can be more easily understood than natural creations because they are the products of the human will. This view was common in the seventeenth century, for example, where philosophers like Hobbes and Locke, under the strong influence of the Cartesian idea that the reflective individual has privileged access to the contents of their own mind, held that only this individual can really know 'the ghost in the machine' in Gilbert Ryle's memorable phrase. Knowing one's own motivations and understanding one's behaviour guarantees nothing, however, about one's understanding of the complexities of human interaction in the social and political arena. In any case, in a post-Freudian age the Cartesian view must be regarded as questionable. We might be confused, or wrong, or we might deceive ourselves about our motivations and purposes. For all we know Bentham might have been right when he insisted that 'it is with the anatomy of the human mind as with the anatomy and physiology of the human

body: the rare case is, not that of a man's being unconversant, but of his being conversant with it' (in *Jeremy Bentham's Economic Writings* 1954, vol. III: 425). In short, the human capacity to shape human nature is a product of how well we can understand and control the causal mechanisms that lead human traits to be what they are. This is contingently related, if it is related at all, to whether a particular trait is a product of biology, culture, some combination of the two, or some third thing.

For all the attention it has received from political philosophers over the centuries, the nature/nurture controversy is a red herring in a second respect as far as politics is concerned. Since human beings are naturally conventional creatures who often achieve biological adaptation through social learning, the distinction between what is natural and what is cultural in human behaviour is not merely difficult to pin down in practice, but impossible to get at in principle. Perhaps partly for this reason, in recent years much of the discussion in Anglo-American political and moral philosophy has turned away from the nature/nurture debate towards requiring principled justifications for any differences among persons that have political consequences, regardless of their origin. John RAWLS is perhaps more responsible for this than any other single figure. In *A Theory of Justice* (1971) he makes the case that differences in talents and abilities among persons, whether natural or cultural in origin, are 'morally arbitrary'; that is, they are products of luck either in the genetic lottery or in the milieu into which one happens to be born. In either case, the differences are not chosen or produced by actions for which the relevant agents can reasonably be held responsible. By the same token, it seems unfair that benefits should accrue to persons differentially in virtue of differences in their talents and abilities, whether such differences are rooted in nature, culture or both.

Making the Rawlsian move has the effect of socializing human capacities regardless of their origins (at least as a normative matter), and although it is exceedingly difficult to find a principled basis on which to resist his reasoning, it generates problems that are in many ways as difficult as those that it resolves. A person might find it both rationally undeniable and psychologically impossible to accept that nothing they do or achieve is the autonomous result of their own efforts. Analogously, it might be argued that for both individual and species some fictions about individual responsibility for different outcomes may be required for human reproduction and wellbeing, even if we know them to be fictions. Such beliefs may be indispensable to the basic integrity of the human psyche and necessary for generating and sustaining the incentive to work on which human beings are, after all, critically reliant. As a result, although facts about moral luck and socially produced productive capacities conspire – when confronted – to enfeeble the idea of individual responsibility for outcomes, people may none the less be powerless to abandon it (see RESPONSIBILITY). One interesting strand of modern scholarship by Ronald DWORKIN, Amartya Sen, Richard Arneson and others attempts to grapple with the issues raised by Rawls' discussion of moral arbitrariness, but it has not converged on any single or compelling conclusion.

3 Self-referential versus other-referential conceptions of human nature

A third dimension along which conceptions of human nature vary concerns the degree to which people's interests are linked to the fortunes and perceptions of others. Contrast Ronald Reagan's 1984 election slogan: 'Are you better off now than you were four years ago?' with an employee who says to his employer 'I don't care what I get paid, so long as its more than Jones down the corridor'. The Reagan slogan is based on a *self-referential* conception of human nature; it assumes that people are interested in improving their own fortunes without any necessary reference to anyone else. The latter example is *other-referential*: a person's perception of their interests is intrinsically reliant on the welfare of others. We cannot make a judgment about their welfare without reference to the welfare of others. The distinction between self- and other-referential views operates independently of whether one is a subjectivist and of the basic metric of value along which welfare is judged. For instance, Marx's measure of exploitation is radically other-referential in that it is critically reliant on the proportion of the social surplus that the workers receive as compared with employers. Thus his technical measure of the rate of exploitation may increase even if real wages are increasing and the worker's subjective sense is that his welfare is improving. Rawls, on the other hand, works with a hybrid of self- and other-referential views of human nature in that he argues that rational people will always want to improve the lot of the worst-off individual in society, relative to what it was before, even if this means that who is the worst off changes.

Whether one thinks human nature is basically self- or other-referential has substantial implications for politics and distributive justice. Utilitarians, both classical and neoclassical, tend to think of people as self-referential maximizers who want to get on as high an indifference curve as possible without reference to anyone else, although there is no necessary reason that this be so. Aristotelians like Alasdair MACINTYRE, on the other hand, are

necessarily committed to other-referential views. For them what people value above all is to be valued by others whom they value. 'She's a cellist's cellist' is an appellation we intuitively grasp, and to the extent that it captures something fundamental about what motivates people, models of individual maximization that ignore it will be descriptively misleading and morally unsatisfying. In this connection it is worth noting that in Hegel's (1807) *Phenomenology* the argument is made that slavery is an unstable set of social arrangements not merely because the slave can eventually be expected to resist oppression, but also because the master will find it unsatisfying; he needs recognition from someone whom he values (see Hegel, G.W.F.).

Whether and to what extent human nature is substantially self-referential is not to be confused with whether and to what degree people are selfish. Although self-referentially motivated people may typically be indifferent – at best – to the fortunes of others; other-referential motivations may be more or less selfish. The demand to be paid 'more than Jones', 'the same as Jones' or 'less than Jones' are all other-referential in character, although they vary considerably on the dimension between selfish and altruistic motivation. Sadists and rapists exhibit what economists refer to as 'interdependent negative utilities' in that their wellbeing is intrinsically linked to the suffering of others; so too does the divorcing spouse whose utility increases if a dollar is taken out of the pocket of their spouse and burned. These are all other-referential types of motivation, no more or less than are the motivations of those who seek and experience increased happiness at another's happiness or success. In short, the self-referential/other-referential dimension refers to the structure of human psychology rather than its content. This is not to say that the structure has no implications for content. In particular, to the extent that people are other-referentially motivated, their behaviour and aspirations will tend not to be captured by rational agent models adapted from microeconomics, which rest exclusively on self-referential assumptions about human psychology. People who find arguments based on rational agent models unsatisfying descriptively or morally tend to be sceptical of the extent to which self-referential assumptions capture important dimensions of the human condition. Whether or not such scepticism is warranted is in the end an empirical question; it will not be settled by armchair reflection (see Rational choice theory).

4 'Political' versus 'metaphysical' conceptions of human nature

Given the enduring – perhaps endemic – disagreements about human nature it is perhaps unsurprising that some political philosophers have sought to develop political theories assuming as little as possible about it. One strategy that has been extensively explored since the 1960s is to try to seek political principles that are neutral between different views of human nature and conceptions of the human good. Some of Rawls' earlier formulations of his project were understood thus, and Bruce Ackerman, Charles Larmore and others subsequently attempted to formulate different neutrality arguments (see Neutrality, political). By the 1990s a fairly broad consensus had begun to emerge that neutrality arguments fail, that there is no set of political principles that can be genuinely neutral among different conceptions of human nature and the human good, and that a little digging into allegedly neutral arguments will inevitably bring their assumptions to the surface.

A subtler response to the problem is to abandon the search for neutral political standards, but retain the ambition to develop political principles that may be compatible with as many different views of the human condition as possible. Here the key idea is to try to limit what one might reasonably expect of justification in political theory, and in particular to abandon all aspirations to get at the true or right theory of human nature. This is the strategy adopted by the later Rawls, who asks: which political principles does it make most sense to agree on, given that we know we will never all agree on basic metaphysical questions about the human condition? The answer to which he is drawn is the one that tolerates as many conceptions of the human good as possible, consistent with a 'like liberty for all'. This approach explicitly abandons the agenda of coming up with right answers to questions about human nature, seeking only to tolerate as many answers as possible. It courts the possibility that it may actually lead us not to tolerate the 'true' view of human nature if, for instance, this is embedded only in a fundamentalist religion that also requires that no other views be tolerated. On a 'political not metaphysical' approach, we are not expected – as political theorists – to take any view on the question whether the fundamentalist view is correct; for all we know it might be. However, since we can never know that it is the correct view and we do know that there will always be competing views, it is never rational to accept it as governing our politics. Various difficulties confront this and other attempts to move in the 'political not metaphysical' direction, and some will find the philosophical abdication implied by this strategy impossible to live with. But in a world in which assumptions about human nature are both indispensable to politics and endemically controversial, it is difficult to see how the impulse to turn to institutional, rather than

philosophical, solutions to the problems it creates can reasonably be resisted.

IAN SHAPIRO

HUMANISM, RENAISSANCE

The early nineteenth-century German educator, F.J. Niethammer, coined the word 'humanism', meaning an education based on the Greek and Latin classics. The Renaissance (for our purposes, Europe from about 1350 to about 1650) knew no such term. The Renaissance had, instead, the Latin phrase *studia humanitatis* (literally 'the studies of humanity'), best translated as 'the humanities'. The Renaissance borrowed the phrase from classical antiquity. Cicero used it a few times, but it was the later grammarian Aulus Gellius who clearly equated the Latin word *humanitas* with Greek *paideia*, that is, with the classical Greek education of liberal learning, especially literature and rhetoric, which was believed to develop the intellectual, moral and aesthetic capacities of a child (*pais* in Greek; hence *paideia*).

Renaissance humanists understood by *studia humanitatis* a cycle of five subjects: grammar, rhetoric, poetry, history and moral philosophy, all based on the Greek and Latin classics. A humanist was an expert in the *studia humanitatis*. The dominant discipline was rhetoric. Eloquence was the highest professional accomplishment of the Renaissance humanists, and rhetorical interests coloured humanists' approach to the other parts of the *studia humanitatis*. The Renaissance humanists were the successors of the medieval rhetorical tradition and the resuscitators of the classical rhetorical tradition. Renaissance humanism was, in the words of P.O. Kristeller, 'a characteristic phase in what may be called the rhetorical tradition in Western culture' ('The Humanist Movement' 1955).

Renaissance humanism was neither a philosophy nor an ideology. It reflected no fixed position towards religion, the state, or society. Rather it was a cultural movement centred on rhetoric, literature and history. Its leading protagonists held jobs primarily as teachers of grammar and literature. Outside academia, they served as secretaries, ambassadors and bureaucrats. Some were jurists. The Renaissance humanists reasserted the importance of the humanities against the overwhelming dominance of philosophy and science in medieval higher education. As humanism penetrated the wider culture, it was combined with other disciplinary interests and professions so that one found humanist philosophers, physicians, theologians, lawyers, mathematicians and so forth.

Ideologically humanists were a varied lot. Some were pious, some were not. Some were interested in philosophy, most were not. Some became Protestants, others remained Catholic. Some scorned the vernacular while others made important contributions to it. Humanism influenced virtually every aspect of high culture in the West during the Renaissance. Depending on the humanist under discussion, one can legitimately speak of Christian humanism, lay humanism, civic humanism, Aristotelian humanism and other combinations.

Humanism had a profound effect on philosophy. Writing outside the philosophical establishment, humanists sought to make philosophy more literary in presentation and more amenable to rhetorical concerns. No less importantly, they recovered and translated into Latin a large reservoir of Greek classical texts unknown or ignored in the Middle Ages. Platonism, Stoicism, Epicureanism and scepticism all experienced revivals. The humanists challenged medieval Aristotelianism by offering new Latin translations of Aristotle that in some respects amounted to fresh interpretations. They also significantly enriched the Aristotelian corpus by translating the *Poetics* and the late ancient Greek commentators on Aristotle.

Renaissance humanism arose out of the peculiar social and cultural circumstances of thirteenth-century Italy. It came to maturity in Italy in the fifteenth century and spread to the rest of Europe in the sixteenth. It gradually lost its vitality in the seventeenth and eighteenth centuries as its focus on Latin eloquence became out of date in a world increasingly won over to the vernacular literatures and new science. In the nineteenth century, it did not so much die as become metamorphosed. Renaissance humanism sloughed off its rhetorical

impulse and became modern scholarly classicism. Today the word humanism has taken on new connotations, but the heritage of Renaissance humanism runs deep in our culture. As long as we continue to value literature and history, and the functional skills and cultural perspective attached to these disciplines, every educated person by training will be a humanist in the Renaissance sense.

JOHN MONFASANI

HUMBOLDT, WILHELM VON (1767–1835)

Along with Schiller and Goethe, Humboldt was one of the chief representatives of Weimar classicism, a movement that aspired to revive German culture along the lines of ancient Greece. Humboldt's philosophical significance resides mainly in two areas: political theory and the philosophy of language. In political theory he was one of the founders of modern liberalism; and in the philosophy of language, he was among the first to stress the importance of language for thought, and of culture for language.

FREDERICK BEISER

HUME, DAVID (1711–76)

Introduction

David Hume, one of the most prominent philosophers of the eighteenth century, was an empiricist, a naturalist and a sceptic. His aim, as stated in his early masterpiece, *A Treatise of Human Nature* (written and published when he was in his twenties), was to develop a 'science of man' – what would now be called a cognitive and conative psychology – that would provide a philosophical foundation for the sciences, both those that concern human life (such as 'logic, morals, criticism, and politics') and those that are merely investigated by human beings (such as 'mathematics, natural philosophy, and natural religion'). Although the Treatise itself received relatively little attention upon its publication in 1739–40, Hume's philosophical views attracted greater attention as a result of *An Enquiry concerning Human Understanding* (1748), *An Enquiry concerning the Principles of Morals* (1751), various essays and his posthumously published *Dialogues Concerning Natural Religion* (1779). He was also noted as a historian, diplomat and essayist on political and economic topics.

One aspect of Hume's empiricism was methodological, consisting in his endorsement and practice of 'the experimental method' requiring that claims in his science of man be derived from and supported by experience rather than from intellectual ratiocination independent of experience. In this, he saw himself as following in the tradition of Locke and as standing against the excesses of earlier philosophers such as Descartes. But whereas natural philosophers (that is, natural scientists) such as Newton could simply design experiments to answer questions about the behaviour of bodies in particular circumstances, the premeditation of attempts to place the mind in a particular situation could alter the mind's natural operations, he maintained, so that we must 'glean up our experiments in this science from a cautious observation of human life, and take them as they appear in the common course of the world, by men's behaviour in company, in affairs, and in their pleasures' (THN Introduction). Another aspect of his empiricism was conceptual, consisting in his doctrine – itself defended through use of the experimental method – that all ideas, and hence all concepts, must be copied from 'impressions', that is, sensory or internal experiences. He thus also followed Locke in rejecting Cartesian 'innate ideas'.

Hume's pursuit of the experimental method proved, in his conduct of it, to support his methodological empiricism as well; for he claimed to find that all beliefs concerning 'matters of fact and real existence' – as distinguished from pure 'relations of ideas' such as mathematics – depend on the relation of cause and effect, and that relations of cause and effect, in turn, can only be discovered through the observed constant conjunction of events of one type with events of another type. Yet although we (philosophers included) easily suppose that we perceive a 'necessary connexion' binding an effect to its cause in such a way that it would be a contradiction for the one not to follow the other, there is in fact no such contradiction; for a cause and its effect are always two distinct events, either of which can be conceived to occur without the other. The attribution of a 'necessary connexion' to causes and effects results from the mind's projection on to them of its own feeling of mental determination to make an inference from the occurrence of an event of the one type to an event of the other after experience of their constant conjunction. Such inferences are not themselves founded on any process of reasoning concerning the uniformity of nature, for the denial of the uniformity of nature is not contradictory, and any attempt to defend the uniformity of nature by

appeal to past experience would assume what the reasoning was supposed to establish. Instead, they are based on the mental mechanism of 'custom or habit'. While he endorses – and engages in – reasoning, Hume finds that many operations of the mind, including those involved in volition and morals, owe less to reason and more to other features of the mind's operations than might have been supposed.

Hume's naturalism consisted in his determination to treat the human mind as a part of nature, equally susceptible to scientific investigation and equally subject to ordinary causal laws, without invoking either special natural properties or supernatural entities. Indeed, he emphasized the extent to which human mental operations resemble those of animals. He was a determinist concerning both physical and mental events, holding that a given set of circumstances will always produce the same outcome in accordance with uniform laws of nature. Unlike Spinoza, however, he held this doctrine only because he thought it was supported by experience as a likely extrapolation from the successes of scientific enquiry. His naturalism is evident in his treatment of morals, which he explains as deriving from the human 'moral sense' – that is, the capacity to feel a distinctive kind of approbation and disapprobation when considering features of character – that is activated primarily by natural sympathy with those who are affected by the character traits in question. Virtue and vice acquire their central role in human life primarily through their ability to inspire love and pride, hatred and humility. Hume did not ever explicitly deny the existence of a deity, and he allowed that the hypothesis of an intelligent cause for the universe has a natural persuasive force. However, he forcefully criticized arguments for the existence of God, for religious miracles, for an afterlife with rewards and punishments, and for a deity's moral goodness or moral concern. He regarded religion as being largely pernicious for both enquiry and morals.

Hume did not use the terms 'empiricist' or 'naturalist'. He did, however, call himself a sceptic. His scepticism was the consequence of his discovery, in the course of his investigations, of the many 'infirmities' of human cognitive nature, including its inability to defend by reasoning many of its own most fundamental operations. While he held that intense consideration of these infirmities can produce a state of extreme but temporary doubt and bewilderment, the scepticism that he endorsed and sought to practice was 'mitigated' in degree, consisting in a certain diffidence and lack of dogmatism in all of his judgments. In addition to this general mitigated scepticism, however, he also recommended a complete suspense of judgment concerning matters entirely beyond our experience – such as cosmological speculation concerning 'the origins of worlds'.

1 Life and writings

David Hume was born in Edinburgh on 26 April 1711, just four years after the formal union of England and Scotland that created Great Britain. The influx of Isaac Newton's natural science and John Locke's philosophy into the Scottish universities paralleled the political union (see Newton, I; Locke, J.). Both Newton and Locke were widely seen as championing an empirical approach to knowledge in which observation and experimentation were to drive, constrain and determine theory. This approach stood in broad contrast with the readiness of many Continental philosophers of the seventeenth century – such as René Descartes, Nicholas Malebranche, Benedict de Spinoza, and Gottfried Wilhelm Leibniz – to allow high-level theoretical commitments to structure our understanding of the world and to determine the interpretation of sensory observations. Of particular concern to eighteenth-century philosophers were questions about the contents and faculties of the mind, causal reasoning, causal necessity, free will, God, the external world, personal identity, scepticism, motivation, the foundations of morality and political obligation. Hume was to make important contributions on each of these topics.

Hume was the youngest of three children. His mother, Katherine, was the daughter of Sir David Falconer, President of the College of Justice; his father, Joseph Home, practised law and was related to the Earls of Home. (Hume altered the spelling of his surname as a young man in order to aid its proper pronunciation.) The family maintained a modest estate, Ninewells, located in Berwickshire near the English border. Joseph Hume died in 1713, and young David was raised by his mother, a

steadfast Calvinist who devoted herself to her children and never remarried. (She reportedly once declared, 'Our Davie is a fine, good-natured crater [creature], but uncommon wake-minded'; the now-obscure final adjective of this famous but perhaps apocryphal remark has been interpreted variously as meaning 'stupid', 'weak-willed', and 'intellectually alert'). Hume greatly admired his mother, but he rejected all religious commitments from an early age.

Between 1723 and 1725, Hume studied at the Edinburgh Town College – now the University of Edinburgh – with his older brother John. Among his subjects of study were Greek, logic, metaphysics and Newtonian 'natural philosophy'. From 1725 until 1734, he resided at Ninewells – preparing for a legal career, although he later allowed (in his 'My Own Life') that he read more philosophy than law. An attempt at a business career in 1734 under the tutelage of a merchant in Bristol ended in disappointment after a trial of just a few months, and the 23-year-old Hume moved to rural France to live cheaply while pursuing philosophy.

After a year in Rheims, Hume settled in La Flèche, site of the Jesuit college at which Descartes had been educated. He took full advantage of the college library as he devoted himself to writing, and in 1737 he moved to London to pursue the publication of the result, which is now regarded as his most important philosophical work. The work was *A Treatise of Human Nature* (cited here as THN), described in its subtitle as 'An Attempt to introduce the experimental method of Reasoning into Moral Subjects'. By 'moral subjects' Hume meant not only ethics, but human nature and human affairs more generally; the book's aim, as he described it in the Introduction, was to provide a 'science of man' – that is, what we would now call a cognitive and conative psychology. Because much of human knowledge *concerns* human beings and all of it is *acquired by* human beings using their human cognitive faculties, Hume proposed that such a science would provide 'a foundation almost entirely new' for all of the sciences. Just as Thales' inauguration of the study of non-human nature was followed by Socrates' inauguration of the study of human nature, he wrote, so too Francis Bacon's application of the experimental method to the study of non-human nature had been followed by the application of the experimental method to the study of human nature by Locke and some other 'late philosophers of England' (see THALES; SOCRATES; BACON, F.). The unstated implication was that, just as Newton had perfected the former, Hume would endeavour to perfect the latter. Book I ('Of the Understanding') and Book II ('Of the Passions') of the Treatise were published together in 1739, anonymously; Book III ('Of Morals') appeared, also anonymously, in the following year.

Despite his efforts to obtain a wide readership for the book – he even composed an anonymous review, *An Abstract of a Treatise of Human Nature*, explaining some of its leading points and focusing particular attention on its central account of causal inference in Book I – the book's reception was a great disappointment to him. Although it did receive a few (largely negative) reviews, he wrote later, that the *Treatise* 'fell deadborn from the press, failing to elicit even a murmur from the zealots' ('My Own Life'); and indeed, the initial printing of 1,000 copies did not sell out during Hume's lifetime. Returning to Ninewells to live with his mother and brother, he turned his hand to essay writing, and his *Essays, Moral and Political* (two volumes, 1741–2) were somewhat better received. In 1745, he was considered for a professorship (of 'moral and pneumatical philosophy') at the University of Edinburgh. Although he was friendly with many of the more liberal clergy of Edinburgh, he was denied the chair because of the perceived anti-religious tenor of the Treatise. In the course of his candidacy, he wrote a pamphlet, published as *A Letter from a Gentleman to his Friend in Edinburgh*, rebutting theistically motivated objections to the book, including the charge of denying the causal maxim that every event has a cause.

Following the disappointment at Edinburgh, Hume took a position as a tutor and caretaker to the psychologically troubled young Marquis of Annandale, a post that lasted for a year. There followed several years travelling as an aide and secretary to General St Clair (a distant relative), first on a military expedition – for which Hume's reading in law allowed him to serve in the administration of military justice as Judge Advocate – that was originally projected to be against French Canada but was ultimately directed against the coast of France (1746), and then on a series of diplomatic missions to Vienna and Turin (1747–8). In 1748 he published *An Enquiry concerning Human Understanding* (cited here as EHU), which he later described as a 'recasting' of the material of Book I of A Treatise of Human Nature in response to his judgment that the poor reception of the *Treatise* had to do 'more with the manner than with the matter' ('My Own Life') of the earlier work. He did, however, affix an 'advertisement' in 1775 to his collected Essays and Treatises on Several Subjects – which included the Enquiry but not *A Treatise of Human Nature* – asking that his philosophy not be judged on the basis of 'that juvenile work'. This request was a response to the use of substantial quotations from the Treatise made by 'that bigotted silly Fellow, Beattie' (*The Letters of David Hume*

1932, Letter 509) in Beattie's highly critical and largely uncomprehending 1770 work, *An Essay on the Nature and Immutability of Truth* (see BEATTIE, J.).

Whereas the *Treatise* had aimed at a rich and intricate 'science of man', the *Enquiry* aimed at a more streamlined 'mental geography' that omitted many elements and complexities from Book I of the earlier work in order to focus on the explanation of causal inference and its application to a selection of other topics. The often dramatic and sometimes combative tone of the *Treatise* gave way to a more urbane and conciliatory tone in the *Enquiry.* For example, in the *Treatise* the defence of the 'doctrine of necessity' against the 'doctrine of liberty' concerning the will becomes in the Enquiry, through a simple terminological modification with no change of substantive position, a 'reconciling project' between the two doctrines. But while the *Enquiry* was rhetorically more conciliatory than the *Treatise*, it was at the same time much more directly subversive, for the three applications of his theory of causal inference on which Hume chose to concentrate – concerning the freedom and necessity of the will, rewards and punishments in an afterlife, and miracles – all had obvious anti-religious implications, and he described the goal of the work in its opening section precisely as that of disentangling philosophy from the grip of 'superstition'. Indeed the section of the *Enquiry* devoted to the topic of miracles – a topic that he had cautiously excised from the manuscript of the *Treatise* – soon became the most notorious piece of writing of his career (see MIRACLES). The year 1748 also saw the publication of his *Three Essays Moral and Political*; and at the end of the year, he returned from General St Clair's service to Ninewells.

In 1751, Hume published *An Enquiry Concerning the Principles of Morals* (cited here as EPM), a 'recasting' of Book III of the *Treatise* organized around the question of what constitutes virtue or personal merit, and a work that he later described as 'of all my writings, incomparably the best'. Anxious for a return to city life, he moved to Edinburgh and set up a household with his sister, Katharine. In the following year, he published *Political Discourses* (which included essays on topics in what would now be considered economics) and was again passed over for a professorship in philosophy – this time at the University of Glasgow, where his friend Adam SMITH was vacating the Chair of Logic to take up the Chair of Moral Philosophy. Hume was obliged to accept instead the position of Librarian of the Faculty of Advocates' Library (which developed into what is now the National Library of Scotland) in Edinburgh. The primary advantage of the position lay in the ready access it provided him to the library itself, which he used to write what ultimately proved to be a very popular six-volume *History of England*, published between 1754 and 1762. While serving as Librarian, he also published, in 1753, *Essays and Treatises on Several Subjects*, a two-volume collection of his previously published work that enjoyed many editions, and, in 1757, Four Dissertations, consisting of 'The Natural History of Religion', 'Of the Passions', 'Of Tragedy' and 'Of the Standard of Taste'. ('Of the Standard of Taste', devoted to the topic of aesthetic judgment, was written to replace two essays – 'Of Suicide' and 'Of Immortality', both finally published only posthumously – that Hume cautiously decided at the last moment to suppress. He had first consented to their inclusion, in turn, in order to replace a dissertation on 'the metaphisical Principles of Geometry', now lost, that a friend had already convinced him to withdraw from the volume.) After completing sufficient research for his History, he resigned the librarianship in 1757. During the last several years of his term, he had been donating his salary to the blind Scottish poet Thomas Blacklock as the result of a dispute in which the library curators had rejected, on grounds of indecency, three French books that Hume had ordered.

In 1763, Hume was invited to serve as secretary to the British ambassador in Paris, Lord Hertford, and after some hesitation, he accepted. French intellectuals admired him for his philosophical scepticism and criticism of religion, his skill as a literary stylist and his sociable character; he was quickly lionized as 'le bon David' by French salon society. Among his friends were the *philosophes* DIDEROT, d'Alembert and Baron d'Holbach. When Lord Hertford took a new post in Ireland, Hume was left in charge of the embassy until the arrival of a new ambassador. When he returned to Edinburgh in 1766, mutual friends prevailed upon him to take the controversial philosopher Jean-Jacques ROUSSEAU (who was no longer welcome in Switzerland) to Britain with him. Hume arranged on Rousseau's behalf the rental of a country house in England. Rousseau soon grew unhappy and suspicious however, and attacked Hume's motives, publicly alleging (apparently on the basis of a satirical piece written by Hume's friend Horace Walpole) that Hume was trying to ruin his reputation. Hume responded, despite his dislike of literary controversies, by writing and circulating a defence of his conduct in the case.

From 1767 to 1769, Hume held a government post as Undersecretary of State for the Northern Department – a position that, ironically enough, required him to give formal government approval to ecclesiastical appointments in Scotland. He returned to his many friends in Edinburgh in 1769. In 1775,

he became aware that he was suffering from intestinal cancer and he died the following year, composing in his final weeks the brief autobiographical essay 'My Own Life' ('this funeral oration of myself', he called it) and impressing all those around him with his cheerfulness and good humour in the face of his impending demise. He left behind the completed manuscript of his *Dialogues Concerning Natural Religion* – on which he had been working for many years and which he had meant to publish only posthumously – with a request that Adam Smith see to its publication. After Smith declined the request to publish the controversial work, it was published instead by Hume's nephew. Smith did, however, write a moving remembrance of Hume, which he concluded with these words: 'Upon the whole, I have always considered him, both in his life-time, and since his death, as approaching as nearly to the idea of a perfectly wise and virtuous man, as perhaps the nature of human frailty will permit.'

2 The contents and faculties of the mind

Hume calls all of the contents of the mind *perceptions*, which he distinguishes as *impressions* and *ideas*. Ideas differ as a class from impressions not in their intrinsic content or character but rather in their lesser 'force and vivacity': in sensing or feeling, the mind has impressions, while in thinking, it has ideas. (He thus uses the term 'idea' more narrowly than do Descartes and Locke, who use the term in a way roughly equivalent to Hume's use of 'perception'.) Perceptions – both impressions and ideas – may also be distinguished as *simple* and *complex*: the former have no perceptions as parts, whereas the latter are composed of simpler perceptions. These distinctions allow the formulation of one of Hume's most fundamental principles: that all ideas are either copied from resembling impressions or composed of simpler ideas that are copied from resembling impressions. He cites as evidence for this principle (sometimes called the *Copy Principle*) the mind's possession of simple ideas corresponding to its simple impressions, the temporal priority of impressions over their corresponding ideas, and the absence of ideas of particular kinds in the minds of those who have never had the corresponding impressions (THN 1.1.1; EHU 1). This principle plays a role in many of Hume's most important arguments on a wide variety of topics, and it also gives rise to a methodological directive: where the character of an idea is unclear or uncertain, trace it to the more forceful and vivacious impression from which it is derived in order to bestow clarity on the idea. Similarly, Hume argues, if one suspects that a term is being used without a meaning – that is, without standing for any idea – the inability to find a corresponding impression may serve to confirm the suspicion.

Within the class of impressions, Hume draws a further distinction between *impressions of sensation* and *impressions of reflection*. The former, which include impressions of colour, taste, smell, sound, heat and touch, have immediate causes that are external to the mind. The latter, which include the passions, moral sentiments, aesthetic sentiments and other internal feelings of the mind, arise as a result of other perceptions, typically ideas – for example, hatred and anger may arise from thinking of pain or harm caused by another. Within the class of ideas, he distinguishes between those that are *particular* and those that are *abstract*. For although he asserts (against Locke and with George BERKELEY) that all ideas are fully determinate in their own nature, he maintains that an idea can acquire a general signification through its association with a word or term that disposes the mind to 'revive' or 'survey' similar ideas as needed in cognitive operations (THN 1.1.7). Such an idea thereby becomes an 'abstract' idea – what we would call a concept.

Abstract ideas, for Hume, may be of kinds of *substances*, *qualities* or *modes* of things, or of *relations* between things. Relations are respects in which two or more things may be compared. While he distinguishes seven general kinds of 'philosophical relations', relations of three of these kinds can also function as 'natural relations' – by which Hume means that the holding of the relation between things can serve as a natural principle of mental association, leading the ideas of the related things to succeed one another in the mind or be combined into complex ideas (such as those of substances). These 'natural relations' are *resemblance*, *contiguity in space or time*, and cause and effect. Whereas Locke had appealed to 'the association of ideas' chiefly to explain error and insanity, Hume dramatically expands its explanatory role in normal cognitive functioning so as to make it a kind of mental analogue of the fundamental Newtonian attractive force of gravitation, but one operating on perceptions rather than on bodies.

In the course of analyzing the operations of the human mind, Hume discusses a number of cognitive faculties. In addition to *sensation* and *reflection*, which are faculties for having impressions, Hume distinguishes two faculties for having ideas. *Memory* is a faculty for having ideas that retain not only the character but also the order and a large share of the original force and vivacity of the impressions from which they are copied. The *imagination*, in contrast, does not retain this large share of the force and vivacity of the original impressions and is not constrained to preserve their order; instead, the

imagination can separate and recombine ideas freely. Because it is a faculty for having ideas, the imagination is, like memory, fundamentally a representational faculty. Such additional cognitive faculties as *judgment* and *reason* are nevertheless functions of the imagination, in Hume's view, because they ultimately constitute particular *ways* of having ideas. This, in turn, is because *belief* itself, in which judgment consists and which constitutes the characteristic outcome of reasoning, is itself a lower degree of force and vivacity, or "liveliness," below that of impressions and memory.

Notably absent from Hume's account of cognitive faculties is any further representational faculty of *intellect*, of the kind proposed by such philosophers as Descartes, Malebranche, Spinoza, Leibniz – that is, a representational faculty whose representations are not derived from sensory or internal experience and which can serve as the basis for a higher kind of cognition than mere experience can provide. Hume's adoption of the Copy Principle constitutes a rejection of such a faculty, for it commits him to accounting for all human cognition exclusively in terms of representations that are images of sensory and inner impressions.

While Hume uses the term 'imagination' in a wide sense to designate 'the faculty by which we form our fainter (that is, non-memory) ideas', he also carefully distinguishes a narrower sense of the term as well, according to which it is 'the same faculty, excluding only our demonstrative and probable reasonings'. *Demonstrative reasoning*, as he characterizes it, depends only on the intrinsic content of ideas; accordingly, whatever is demonstrated has a denial that is contradictory and literally inconceivable, and the result of demonstrative reasoning is *knowledge*, in a strict and technical sense derived from Locke. All other reasoning – resulting not in knowledge, in this technical sense, but in *probability* – is *probable reasoning*, the investigation of which is a central task of Hume's philosophical project. Given this narrower sense of 'imagination' as excluding reasoning, Hume can and often does ask whether a particular feature or content of the mind derives from the senses, reason or the imagination. One of the most general theses of the *Treatise* is that the character of human thought and action is determined to a very considerable extent by features of the imagination in this narrower sense.

In contrast to the understanding are the *passions*, which determine much of human conative nature. What Hume calls the direct passions – including joy, grief, desire, aversion, hope and fear – arise immediately from 'good or evil, pleasure or pain'; the indirect passions arise also arise from pleasure and pain, but 'by the conjunction of other qualities'. Among the most important *indirect passions* are pride, humility, love and hatred. Each of these four indirect passions has a characteristic and natural *object*, either oneself (as in the case of pride and humility) or another person (as in the case of love and hate); this object is that to which the passion directs the thought of the person undergoing it. These indirect passions arise through a process of conversion (called 'the double relation of impressions and ideas'), whereby a pleasure or pain is transformed into a resembling passion when the cause of the pleasure or pain is closely associated with the object of the passion. Voluntary action, for Hume, is the result of *the will*, or volition, which is itself just another impression of reflection, typically prompted by desire or aversion - which may, in turn, be prompted by other passions. The *moral sentiments* of approbation and disapprobation arise from reflection on traits of character – ongoing motives, dispositions and tendencies – and constitute the source of moral distinctions, much as the sentiments of *beauty* and *deformity* constitute the source of aesthetic distinctions. Indeed, Hume characterizes virtue as a kind of 'moral beauty'.

3 Causal reasoning

Seventeenth- and eighteenth-century philosophers offered many different views of the nature and extent of causal power. Descartes, for example, held that causes must contain at least as much 'perfection' as their effects and that the laws of nature can be deduced from God's immutability, while Malebranche followed the suggestion of Descartes' doctrine that God's conservation of the universe is equivalent to continuous re-creation and the implications of the proposition that causes must be connected by necessity with their effects to propose that only God has genuine causal power. Spinoza held that the laws of nature could not have been otherwise and can be discerned by the intellect, while Leibniz denied the possibility of causal interaction between substances. Locke found some but not all kinds of substantial interaction to be unintelligible, while Berkeley held that the only causal power lies in the volition of minds, either divine or finite, to produce ideas.

Of the two kinds of reasoning that he distinguishes, it is probable reasoning, Hume holds, that predominates in human life, yet he finds that it has received relatively little investigation; and it is because it has been so little investigated, he thinks, that there is so much philosophical confusion concerning the nature and extent of 'the efficacy of causes'. All probable reasoning, he argues, depends on the relation of cause and effect: whenever we infer the existence of some matter

of fact that goes beyond the content of present perceptions or memories, it is always on the basis of an implicitly or explicitly supposed causal relation between what is represented by a present perception or memory and the conclusion we draw from it (THN 1.3.2; EHU 4). Yet although all probable reasoning is thus also causal reasoning, the causal relation between distinct things or events seems itself difficult to understand: causes precede their effects in time and are spatially contiguous to them (at least when they have spatial locations at all), but we also suppose that causes and effects have a 'necessary connexion' of some kind. In order to understand fully what the causal relation is, Hume holds, we must first understand the nature of the probable inferences that 'discover' it.

Contrary to those who hold that causal relations can in principle be discerned through pure thought alone, by means of the intellect, Hume argues that the attribution of causal relations always depends essentially on experience – in particular, experience that an event of one kind is regularly followed by an event of a second kind, which he calls their 'constant conjunction'. Any event may be conceived to follow any other event (that is, the imagination can form an idea of it), and prior to experience there is no basis to suppose anything about what will actually follow a given event. Although it may well seem that some causal relations – such as the communication of motion by impact central to the 'mechanistic' natural science of the seventeenth and eighteenth centuries – are so 'natural' that we could anticipate them prior to any experience of them, this is only because early and constant experience has rendered them so very familiar. A probable inference occurs when, following experience of a constant conjunction of events of one type (such as the striking of a match) with events of another type (flame), an impression or memory of a particular event of the one type leads the mind to form a belief in the existence of an event of the other type. Hume's investigation of the way in which this mental transition occurs is the occasion for his famous discussion (originally presented in the *Treatise* (1.3.6) but repeated with slight variations in the *Abstract* and the first *Enquiry* (4)) of what we now call *induction* – that is, the projection that what has held true of observed cases will also hold true of as-yet-unobserved cases.

As a 'scientist of man', Hume asks how this transition actually occurs. He argues first for a negative conclusion: that the transition is not produced – or 'determin'd', as he puts it in the *Treatise* – by reason. His argument for the negative conclusion is as follows. The transition in question spans a gap between what the mind has *experienced* – namely, past constant conjunction between two types of events plus a present impression or memory of an event of one of the two types – and what the mind *concludes*, which is the occurrence of another event of the other type, in conformity to the previously observed regularity. This transition he calls, variously, 'making the presumption' that 'the course of nature continues always uniformly the same', 'supposing that the future will resemble the past' and 'putting trust in past experience'. If reasoning were to cause this transition, Hume argues, it would do so through an inference to a *belief* that nature is uniform, for it is only a conclusion of this kind that could span the gap and so produce the inference. Yet what kind of reasoning could this be? The reasoning could not be demonstrative, for the denial of the uniformity of nature is in every case perfectly conceivable and involves no contradiction. Nor could the reasoning be probable, for, if Hume's previous account of that species of reasoning is correct, all probable reasoning can proceed only if it *already* makes the presumption of the uniformity of nature – which is the very presumption whose causal origin is to be explained. A probable inference thus cannot be the original cause of this presumption, for the making of the presumption is a precondition for all probable inference; and, as Hume puts it in the *Treatise*, 'the same principle cannot be both the cause and effect of another'. Since all reasoning is either demonstrative or probable, and neither demonstrative nor probable reasoning can cause its key transition, probable inference is not 'determin'd by reason'.

In interpreting this conclusion, it is important to recognize that Hume is not questioning whether probable inferences constitute a *species* of reasoning – as of course they do, by his own classification. Rather, he is questioning whether the key transition in such inferences is itself mediated by a *component* piece of reasoning – in something like the way that Locke regards some demonstrative inferences as mediated by other component demonstrative inferences concerning the relations between their parts – or whether the transition is instead made by some other process. It is also important to recognize that Hume's negative conclusion is one about the *causal origin*, rather than the epistemic warrant or justification, of probable inferences. Hume's argument does, however, have important consequences for questions of justification. For if the presumption of the uniformity of nature cannot originally arise from reasoning *at all*, then it cannot be justified by the *way* in which it originally arises from reasoning. Likewise, if the claim that induction will continue to be reliable is a claim of the kind that can only be supported by reasoning that presupposes that induction will continue to be reliable, then any

argument intended to justify the claim that induction will continue to be reliable must beg the question, by presupposing what it seeks to establish. Thus, the much-discussed philosophical problem of how induction *can* be justified is rightly traced to Hume's discussion of probable inference.

Although the mind does not make the presumption of the uniformity of nature by *reasoning to a belief about* that uniformity, it does indeed make the presumption in another way, Hume argues – namely, through the mechanism of 'custom or habit', which is the general tendency of the mind to 'renew' a past operation or action without any 'new reasoning or reflection'. In the case of probable inference, the mind's experience of past constant conjunctions between two types of events is renewed when the mind, upon the impression or memory of an instance of one type, proceeds immediately, without further thought or reflection, to form an idea of an instance of the other. The force and vivacity of the present impression or memory provides a measure of force and vivacity to the idea as well – and this force and vivacity, or liveliness, constitutes the *belief* that the mind reposes in the existence of the object of the idea and serves to explain its ability to affect the will. This habit-based process – which is a feature of the imagination in Hume's narrower sense – thus produces a belief in the *conclusion* of a probable inference without any *intermediate* belief or reasoning about the uniformity of nature at all. Hume's description of this process constitutes his positive answer, complementing his negative answer, to the original question of the nature of the transition.

Hume follows Lockean terminology in characterizing as 'probability' every kind or degree of assurance other than the 'knowledge' that is based entirely on perceiving relations of ideas, but he recognizes that the assurance derived from inferences from experience can be firm and unhesitating. Accordingly, he goes on to distinguish, within the range of probability in the broad Lockean sense, between *proof*, which is the high degree of belief or assurance that results from a full and exceptionless experience of the constant conjunction of two types of events, and mere *probability* in a second and narrower sense. There are three philosophically-approved species of probability (THN 1.3.11-12) in this narrower sense: the *probability of causes*, in which two types of events have been commonly experienced to be conjoined but not exceptionlessly so or only in a small number of cases; the probability of chances, in which there is uniform experience that one of a set of alternatives will definitely occur (such as the landing of a die on one of its faces), but nothing determines the mind to expect one alternative rather than another on a given occasion, so that each alternative acquires only a limited share of assent; and *analogy*, in which belief concerns events that are somewhat similar to, but not exactly resembling, those of which one has experienced a constant conjunction. In addition to these reflectively approved species of probability, Hume also distinguishes several species of *unphilosophical probability* (THN 1.3.13) – that is, ways in which features of the imagination affect the mind's degree of belief or assurance that, upon reflection, we do not approve. In addition, he specifies a set of 'rules by which to judge of causes and effects' (THN 1.3.15), rules that result from reflection on the mind's own operations in probable reasoning and on the successes and failures of past probable inferences. He thus offers a thorough, and provocative, account of non-demonstrative reasoning as always causal and always based on inductive projection from past experience.

4 Causal necessity

On the basis of his account of causal inference, Hume offers an explanation of the 'necessary connexion' of causal relations and provides two definitions of the term 'cause' (THN 1.3.14; EHU 7). It follows from the Copy Principle that, if we have an idea of necessary connection, that idea must be copied from some impression or impressions. When the mind first observes an event of one type followed by an event of another type, however, it never perceives any necessary connection between them; it is only after repeated experience that the mind pronounces them to be necessarily connected. Yet merely repeating the experience of the conjunction of two types of events cannot introduce any new impression into the mind from the objects themselves beyond what was perceptible on the first observation. The impression of necessary connection, from which the idea of necessary connection is copied, must therefore be an internal impression resulting from the respect in which the mind itself changes as the result of experience of constant conjunction. Accordingly, the impression of necessary connection is, Hume concludes, the impression of the mind's own determination to make an inference from an impression or memory to a belief. This impression is often then projectively mislocated in or between the cause and effect themselves, in much the same way that non-spatial tastes, smells and sounds are erroneously located in bodies with which they are associated. Causal relations have a kind of necessity – an unthinkability of the opposite – that is grounded in the psychological difficulty of separating two types of events in the imagination after they have been constantly conjoined in perception and in the

impossibility of believing them actually to be separated. Because of the projective illusion by which the impression of necessary connection is mislocated in the objects, however, we often conflate this causal necessity, Hume explains, with the demonstrative necessity that results from intrinsic relations among ideas. The result, he claims, is philosophical confusion, in which we suppose that we can perceive a necessary connection, amounting to a demonstration, that is intrinsic to causes and effects themselves, and then become dissatisfied when we realize that, at least in some cases, we do not perceive such a connection after all. The dissatisfaction leads to disparate theories concerning how causal powers operate and to restrictions on the range of 'genuine' causal relations. The remedy for this confusion is to realize that we never make probable inferences as the result of perceiving a necessary connection between cause and effect, but rather, that we perceive the (internal impression of) necessary connection precisely because we are disposed to make the inference. Any two types of events are capable of standing in the causal relation to one another – 'to consider the matter a *priori*, any thing may produce any thing' (THN 1.4.5.30) – and only experience can show that which are actually causally related.

Following his account of causal reasoning and causal necessity, Hume defines 'cause' in the *Treatise* both as 'an object precedent and contiguous to another, and where all objects resembling the former are placed in like relations of precedency and contiguity to those objects, that resemble the latter' and as 'an object precedent and contiguous to another, and so united with it that the idea of the one determines the mind to form the idea of the other, and the impression of the one to form a more lively idea of the other' (THN 1.3.14.31; see also EHU 7.33). It may well seem that these two definitions do not serve to pick out the same objects as causes; for objects can be constantly conjoined in fact without being observed to be so, and objects can be taken by observers of unrepresentative samples to be constantly conjoined that are not really so conjoined. In fact, however, both definitions are ambiguous, and in parallel ways. The first definition may be understood either in a subject-relative sense (concerned with what has been conjoined in the observation of a particular subject) or in an absolute sense (concerned with what is constantly conjoined at all time and places). The second definition may likewise be understood either in a subject-relative sense (concerned with what is a basis for association and inference in the mind of a particular subject) or an absolute sense (concerned with what is a basis for association and inference in an idealized human mind that has observed a representative sample of the conjunction in question and reasons in the ways that are philosophically approved). The two definitions then coincide on their subject-relative interpretations – the interpretations that Hume needs when discussing how causal relations constitute a principle of association in individual human minds, which is a matter of what a human mind will *take* to be causally related. The two definitions coincide again on their absolute interpretations – the interpretations that he needs when discussing which pairs of events are in fact causally related. Both definitions are intended to specify the class of ideas of pairs of events that are (either in a particular human mind or ideally) collected under the abstract idea of the relation of cause and effect. If cause-and-effect pairs have something else in common beyond what is captured by these two definitions, it is something inconceivable by the human mind. Interpreters differ on the question of Hume's attitude towards the prospect of such an inconceivable 'something more' – some hold that he rejects it, while some hold that he allows it, and others hold that he assumes it. In any case, however, his conception of constant conjunction as necessary and sufficient for causation is one of the most influential ideas in the history of metaphysics.

5 Free will

The question of whether the human will is free or necessitated is one of the most pressing issues raised by the scientific revolution, one that is central to morality and to the conception of the place of human beings in nature. Hume applies his account of causal reasoning and causal necessity to its solution (THN 2.3.1-2; EHU 8). He holds that his two definitions of 'cause' determine the only two possible requirements for the causal necessity of human actions: (1) constant conjunction with particular types of antecedent conditions and (2) susceptibility to association-plus-inference. Since human actions of particular kinds are constantly conjoined with particular kinds of antecedent motives, character traits and circumstances, he argues, and since these constant conjunctions clearly can and do provide a basis for inference and association on the part of observers, it follows that human actions are causally necessitated. Hume himself is a determinist, holding – on the basis of induction from the past successes of natural science in finding determining causes for events – that every event results from previous conditions in accordance with exceptionless laws of nature. However, what he calls the 'doctrine of necessity' does not require determinism, but rather only the general predictability of human action. For his primary opponents

are not indeterminists, but rather defenders (such as Samuel Clarke) of a distinction between physical causes that necessitate their effects, on the one hand, and 'moral' causes (such as human motivations) that allegedly do not necessitate their effects, on the other. Since we do not feel the impression of necessary connection when we ourselves deliberate and act, Hume argues, we suppose that our own actions are not necessitated. But this conclusion is belied by the constant conjunction of these actions with motives, traits and circumstances, and by the fact that external observers do feel the impression of necessary connection when they predict or infer our actions.

Because we mistakenly suppose that there are two kinds of causation – necessitating and non-necessitating – we also suppose that there is a kind of freedom or 'liberty' that allows constant conjunction, thus supporting association and inference, without causal necessitation. In fact, however, this is impossible; and the only kind of 'liberty' that is opposed to necessity is the *liberty of indifference* or *chance* – that is, the absence of causation and hence of predictability. As a determinist, of course, Hume denies that there is in fact any liberty of indifference at all, although he regards this as a conclusion from experience; but he also denies that anyone would *wish* their actions to be a matter of chance, for then one's actions could stand in no causal relation to one's motives, character and circumstances. The kind of liberty that we do have and want, he argues, is the *liberty of spontaneity* that consists simply in the absence of constraint – that is, the power to have one's acting or not acting determined by one's will. Indeed, both causal necessity *and* the liberty of spontaneity are required for moral responsibility, for one cannot be blamed for what is not caused by one's character, nor for what is contrary to one's will. The fact that the human will is causally determined by motives, traits and circumstances that are themselves, in turn, causally determined by other factors not ultimately subject to the will does not, in Hume's view, interfere in any way with the kind of freedom required for moral responsibility. Hume's treatment of the topic of 'liberty and necessity' is one of the best-known defences of *compatibilism* – the view that the kind of freedom required for moral responsibility is compatible with the causal determination of human deliberation and action – and constitutes an important element in his attempt to integrate the study of human nature into the natural world.

In *An Enquiry concerning Human Understanding*, Hume also considers two 'objections' to religion derived from the bearing of causal necessity and moral responsibility on the doctrine that God is the ultimate cause of the entire universe. The first objection is that this doctrine absolves human beings of responsibility for their crimes, on the grounds that what God causally necessitates must be good; the second is that the doctrine requires us to deny the moral perfection of the deity and to 'acknowledge him to be the ultimate author of guilt and moral turpitude in all his creatures' (EHU 8.33). Against the first objection, Hume argues that we may properly blame human beings for character traits that evoke sentiments of moral disapprobation regardless of their more distant causes. The second objection, however, he pronounces to be beyond the power of human philosophy to resolve – thus, in effect, leaving the objection to stand against theistic cosmology and theodicy.

6 God

In addition to his treatment of free will and divine responsibility, Hume in the first *Enquiry* also draws important consequences from his theory of causal reasoning and causal necessity for the topic of testimony for miracles (EHU 10) – a kind of testimony that, Locke had argued, could provide strong evidence to support claims of divine revelation. Hume first draws from his account of probable inference the conclusion that experience must be our only guide concerning all matters of fact, and that the 'wise' will proportion their beliefs to the experiential evidence. Thus, where there is a proof (in the sense of a widespread and exceptionless experience), the wise place a full reliance; where there is only probability (in the narrow sense distinguished from proof), they repose only a more hesitating confidence. Accordingly, where a proof comes into conflict with a mere probability, the proof ought always to prevail. Hume then applies these general principles to the specific topic of testimony. Testimony cannot possess any inherent credibility independent of its relation to experience; rather, testimony of a particular kind properly carries weight only to the extent that one has experience of the reliability (that is, conformity to the truth) of that kind of testimony. Finally, Hume applies this principle about testimony, in turn, to the special case of testimony for the occurrence of a miracle, understood as a violation of a law of nature. Since regarding a generalization as a law of nature is to regard it as having a proof (in Hume's technical sense), it follows that to suppose an event to be a miracle is, ipso facto, to allow that there is a proof against its occurring. In consequence, testimony for a miracle cannot establish the occurrence of the miracle if there is only a probability, rather than a full proof, that the testimony is reliable. Rather, testimony could establish the occurrence of a miracle only if the falsehood of that testimony

would itself be an even greater miracle – and even in that case, Hume remarks, there would be 'proof against proof', requiring one to look for some greater basis for credibility in one proof than in the other (such as might be found in its 'analogy' with yet other proofs) and resulting in at most a very hesitating acceptance of whichever proof was found to be stronger. In effect, then, Hume argues that one should always accept the least miraculous explanation available for the occurrence of testimony for a miracle.

After arguing for this very high general standard for the credibility of testimony for miracles, Hume goes on to consider the quality of actually existing testimony for miracles, the psychological mechanisms that stimulate the offering and acceptance of false testimony of religious miracles, the high proportion of miracle testimony originating among 'primitive and barbarous' peoples and the counteracting effect of testimony for miracles offered in support of conflicting religions. He concludes from this survey, first, that no actual testimony for miracles has ever met the standard required, nor, indeed, has ever even amounted to a probability; and second, that no testimony could ever render a miracle credible in such a way as to serve to establish the claims of a particular religion.

Another application of Hume's account of causation and causal reasoning in the first *Enquiry* concerns 'providence and a future state' (EHU 11) and is presented in the form of a dialogue between Hume and a 'friend'. Because observed constant conjunction provides the only basis for inferences concerning the unobserved, the friend argues, we cannot infer more in an unobserved cause than we have observed to be required for an observed effect; and hence a dilemma faces those who hold that the reasonable prospect of rewards and punishments in an afterlife provides an essential motive to moral behaviour. For if the present life is not so arranged as consistently to reward the good and punish the evil, then there is insufficient experiential basis to conclude that God will be any more concerned consistently to reward the good and punish the evil in the afterlife. If, on the other hand, the present life is so arranged that the good are consistently rewarded and the evil consistently punished, then the inference to similar rewards and punishments in an afterlife may be reasonable, but the conclusion will be unnecessary to motivate moral behaviour after all – for the present life itself will offer sufficient incentives in its own right. (It might, of course, be suggested that revelation provides a different and independent source of knowledge about the nature of the afterlife; but Hume has also implicitly attacked claims to have trustworthy divine revelation by attacking the credibility of testimony for miracles used to support claims to revelation.) Hume's final remark in the dialogue raises the question of whether, given the uniqueness of the origin of the universe and our lack of experience regarding it, anything at all can be inferred about its cause.

Dialogues Concerning Natural Religion takes up this suggestion in detail, offering an application of Hume's theory of causal reasoning to examine what is often called the 'argument from design', or 'teleological' argument, for God's existence. The character of Demea – representing philosophical theologians such as Samuel Clarke – proposes that the existence of God can be deduced from the need for a necessarily existent being to serve as the cause of the series of contingently existing beings. However, the characters of Cleanthes (a theist who accepts the view that all causal claims can be established only by experience) and Philo (a sceptic who also accepts the view that causal claims can be established only by experience) reject the notion of necessary existence – since anything can be conceived either to exist or not to exist – and agree that a good argument for the existence of God must be based on empirical evidence that the universe is the product of intelligent design. Their dispute concerns the strength of such arguments. Since we have no experience of the creation of universes, Philo argues, we are in a poor position to assess their causes, and explaining the orderliness of the universe by appealing to the activity of an orderly divine mind seems to be an unnecessary step, for the order of the divine mind itself would equally require explanation. If we must speculate, however, there are many hypotheses possible, at least some of which seem to have the advantage over that of intelligent design. Perhaps, for example, the universe arose through a process of animal generation: experience provides many examples of that process giving rise to intelligence, but no examples of intelligence giving rise to the process of animal generation. Furthermore, if we do suppose that the evidence favours the hypothesis that the cause of the universe resembles a human designer, we cannot limit ourselves to the quality of intelligence but will be obliged to treat that cause anthropomorphically – as embodied, gendered, limited and plural, just as we find the designers of complex human artefacts to be.

Yet despite these objections Philo finds himself moved and even confounded by the immediate persuasive power of Cleanthes' statement of the argument from design, despite its 'irregular' character as judged by the standards of proper causal inference. Philo reports himself to be on psychologically stronger ground when he goes on to argue that the existence, nature and distribution of evils in

the world renders it improbable that an intelligent cause of the universe, if there is one, is morally good or concerned to foster human wellbeing. None the less, Philo takes a notably conciliatory tone at the end of the *Dialogues*, conceding that 'the cause or causes of the universe probably bear some remote analogy to human intelligence'. This need not be considered a complete concession to Cleanthes, however, as he has earlier allowed that 'the rotting of a turnip' also bears some remote analogy to human intelligence. While strongly criticizing the pernicious consequences for human society of religious faction and superstition, Philo suggests that the dispute between theists and sceptics is a 'verbal' one, based to a considerable degree on differences of temperament: whereas theists emphasize the admitted analogies between the universe and known products of intelligent design, sceptics emphasize the admitted disanalogies. While commentators continue to dispute the extent to which Philo or Cleanthes can be taken to speak for Hume, it is generally agreed that the Dialogues provide a seminal critique of the argument from design.

7 The external world

The newly mechanistic natural science of the seventeenth and eighteenth centuries sharpened the question of what and how one can know of the external world through sensation. One of Hume's aims in the *Treatise* is to investigate 'what causes induce us to believe in the existence of body' (THN 1.4.2), although he remarks at the outset of the investigation that 'it is in vain to ask, Whether there be body or not? That is a point which we must take for granted in all our reasonings'. He analyses the belief in 'bodies' (physical objects) as the belief in objects that have a 'continu'd and distinct' existence: that is, in objects that continue to exist when not perceived by the mind and that have an existence that is distinct from the mind in virtue of existing outside of it and in causal independence of it with respect to their existence and operations. The 'vulgar' – which includes even philosophers, for most of their lives – attribute a continued and distinct existence to some of what they immediately perceive, even though what they immediately perceive are in fact impressions. The opinion that these impressions have a continued and distinct existence cannot itself be an immediate product of the senses, Hume argues, for the senses themselves cannot perceive the continuation when unperceived, or even the distinct existence of what they perceive immediately; nor can the opinion be a proper subject of inference, since reasoning shows instead that what we immediately perceive are not continued and distinct existences, but dependent and perishing impressions in the mind. The opinion in question must, therefore, depend on features of the imagination (in the narrow sense).

How then does the belief in bodies arise? As Hume explains it, some of our impressions (for example, those of colour, sound, taste, smell and touch) exhibit *constancy* and *coherence*. Constancy is their tendency to return despite interruptions; coherence is their tendency to occur in a certain order and to manifest elements of that order at similar times even through interruption. The coherence of impressions plays a role in the tendency to attribute continued and distinct existence to those impressions, since by means of the supposition of such existence the mind can attribute greater causal regularity to them than would otherwise be possible – and once the mind becomes accustomed to looking for causal regularities, it carries this tendency on even beyond what it originally finds in experience. The primary cause of the attribution of continued and distinct existence to what are in fact impressions, however, is their constancy, Hume maintains. The mind easily confuses a 'perfectly identical' – that is, invariable and uninterrupted – object with a sequence of resembling but interrupted ones, because the feeling to the mind is itself similar in the two cases. Accordingly, the mind attributes a perfect identity to some of its interrupted impressions. At times when the mind becomes aware of the interruption, it seeks to reconcile the contradiction by supposing that the very impressions themselves continue to exist uninterruptedly, distinct from the mind, during the moments when they are not perceived. The force and vivacity of the impressions provides the liveliness required for this supposition to constitute a belief.

The vulgar opinion that the very things we immediately perceive have a continued and distinct existence apart from the mind is not, Hume argues, contradictory or inconceivable; but it can, none the less, easily be shown to be false by a few simple experiments. Pressing one's eyeball, for example, doubles one's visual impressions, thereby showing that they are not causally independent of the mind for their existence or operation, and from this it can be inferred that they do not continue to exist when not perceived. Yet the opinion that there are continued and distinct existences is, Hume asserts, psychologically so irresistible that, far from giving it up, philosophers invent a new theory to reconcile their experiments with it. This is the philosophical theory of 'double existence', according to which sensory impressions are caused by a second set of objects – bodies – that resemble them qualitatively. This theory, Hume argues, has no primary recommendation to the imagination – for the

imagination naturally gives rise instead to the original vulgar view that our impressions themselves are continued and distinct. Nor does the theory have any primary recommendation to reason – for causal reasoning can conclude that an object of a given kind exists only if it has been observed to be constantly conjoined with an object of another kind, yet on the philosophical theory, we directly observe only impressions, not bodies accompanying impressions. When he considers intensely the causal origin of the belief in bodies, Hume reports that he loses confidence in the belief, his earlier claim that we must take it for granted notwithstanding. However, this state of doubt is only temporary, for belief in bodies (in one form or other) immediately returns as soon as one's attention is turned away from the question.

A further problem concerning the content of the belief in bodies arises from what Hume calls 'the modern philosophy' (THN 1.4.4). It is a central contention of the modern philosophy that such qualities as extension, solidity and motion really exist in bodies, but that qualities resembling our impressions of colours, sounds, tastes, smells and tactile qualities (such as heat and cold) do not really exist in bodies. This is, for example, Locke's claim concerning what he calls 'primary' and 'secondary' qualities. Hume judges that there is, among the various arguments of the modern philosophers for this conclusion, one that is 'satisfactory'. It is found that the perception of colour, sound, taste, smell, heat and cold varies with different perspectives and different states of one's body; and hence it follows that bodies cannot have all of the qualities of colour, sound, taste, smell, heat or cold that they are perceived to have. Hence, he argues, from the principle (which is one of his 'rules by which to judge of causes and effect') that 'like effects have like causes', we may conclude that none of these qualities exist in bodies themselves. Yet the qualities of extension, solidity and motion of bodies cannot be conceived without conceiving colours or tactile qualities to fill the extension of the body in which they supposedly occur; hence, it follows that bodies cannot be determinately conceived at all in strict accordance with the modern philosophy. Since this 'satisfactory' argument is a causal one, Hume presents the outcome as a conflict between causal reasoning and 'our senses' – meaning by the latter term, more specifically, the operations of the imagination on impressions of sensation that give rise to the belief in bodies.

8 Personal identity

The second edition of Locke's *An Essay Concerning Human Understanding* (1694) offers an account of the nature of personal identity as grounded not in identity of substance but in 'sameness of consciousness' derived from memory, The account stimulated considerable discussion and controversy, and Hume, in the Treatise takes up the question of personal identity that 'has become so great a question in philosophy, especially of late years, in England' (THN 1.4.6). He rejects the proposal that we are constantly aware of a 'self' that is simple and 'perfectly identical' (that is, invariable and uninterrupted) through time. We have no idea of such a self, Hume argues, appealing to the Copy Principle, for we have no impression of it. Nor can we conceive how our particular perceptions could be related to a substantial self or mind so as to inhere in it, for the supposed concept of a substance in which qualities or perceptions inhere is a mere fiction, invented to justify the association-based tendency to think of what is really a plurality of related but changing qualities or perceptions as having something that bestows simplicity at a time and perfect identity through time on them. Instead, Hume finds, we are aware only of the sequence of perceptions themselves; as he famously puts it, 'when I enter most intimately into what I call myself, I always stumble on some particular perception or other, of heat or cold, light or shade, love or hatred, pain or pleasure. I never can catch myself at any time without a perception, and never can observe any thing but the perception' (THN 1.4.6.3). Accordingly, 'the true idea of the human mind' is that of a 'bundle' of different perceptions related by causation in such a way as to 'mutually produce, destroy, influence, and modify each other'. Because memory reproduces the intrinsic content of earlier perceptions, there is also a considerable degree of resemblance among these perceptions. These perceptions come to constitute an 'imperfect' or 'fictitious' identity, Hume explains, because their many close associative relations of causation and resemblance cause them, when surveyed in memory, to be mistaken for a perfect identity. He draws from this a corollary that has negative implications for immortality and the justice of rewards and punishments in the afterlife – namely, that 'all the nice and subtile questions concerning personal identity can never be decided' because such questions are merely 'grammatical', involving relations susceptible of insensibly diminishing degrees (THN 1.4.6.21).

In the Appendix to the *Treatise* (published with its second volume, containing Book 3), however, Hume expresses dissatisfaction with his previous account of the relations giving rise to personal identity. Because his diagnosis of the problem remains quite general, many interpretations have been offered of the precise basis of his dissatisfaction.

One possible source of dissatisfaction is that his own account of causality, as expressed in his definitions of 'cause', entails that simultaneous and spatially unlocated but qualitatively identical perceptions cannot differ in their causal relations, so that two such perceptions could not exist in two different minds if his account of the 'true idea of the human mind' were correct. In any case, he pronounces the difficulty a further ground for scepticism – that is, for entertaining 'a diffidence and modesty in all my decisions'.

9 Scepticism

As the scientific revolution of the seventeenth century brought a decline in the authority of Aristotle, it also brought renewed interest in ancient scepticism (including Pyrrhonism and the scepticism of the later Academy), and Descartes' methodological scepticism in the *Meditations* helped to make a concern with scepticism central to philosophy. Hume's strategy in the *Treatise* is to complete an investigation of human cognitive faculties, by means of those faculties, before turning to the question of whether the nature of the discoveries made undermines confidence in those faculties themselves. Thus, at the conclusion of Book I of the *Treatise* (THN 1.4.7), Hume surveys a number of considerations conducive to scepticism (to which the additional problem about personal identity from the Appendix to the *Treatise* constitutes an *ex post facto* addition). At the conclusion of the first *Enquiry*, he again surveys and assesses sceptical considerations, although the list only partially overlaps that of the *Treatise*.

Of the general sceptical considerations concerning human cognition (beyond personal susceptibilities to error) reviewed at the conclusion of the *Treatise*, the first lies in the dependence of belief on the 'seemingly trivial' quality of the imagination whereby ideas acquire force and vivacity from impressions by means of probable reasoning, memory and the senses. (It is only here, incidentally, long after his famous account of probable or inductive reasoning, that he draws any connection between it and scepticism in the *Treatise*.) The second lies in the 'contradiction' between causal reasoning and the belief in bodies, with specific qualities, discovered in connection with 'the modern philosophy'. The third consists in the illusion whereby the mind supposes that it discovers real necessary connections intrinsic to causes and effects themselves, even though such connections are in fact inconceivable.

The final sceptical consideration depends on an argument that Hume had earlier discussed in a section entitled 'Of scepticism with regard to reason' (THN 1.4.1). Since reason is a kind of cause, he observes, of which truth is the usual but not unfailing effect, every judgment, with whatever degree of assurance it is held, may be assessed, on the basis of past experience, for the probability that one's faculties operated well – that is (presumably) did not produce too high a degree of assurance – in reaching that judgment. Yet even if one concludes with a high degree of assurance that one's faculties operated well in the initial judgment, one will find at least some low degree of probability that one's original assurance was too high; and this realization should serve to decrease somewhat the original assurance of the first judgment. Furthermore, he argues, a *third* judgment concerning the operation of one's faculties in the *second* judgment will likewise find at least some low degree of probability that one's assurance in making the second judgment – namely, the judgment that one's original assurance in the first judgment was not too high – was *itself* too high. This realization, Hume argues, should properly reduce the assurance of the second judgment – which should, in turn, again reduce further the assurance of the first judgment. Since this process may properly be reiterated indefinitely, and the amount of assurance available in any judgment is finite, the result should, in accordance with the natural operations of the 'probability of causes', be the elimination of all belief.

No such elimination of belief actually occurs, however, even when one aims to employ the probability of causes as scrupulously as possible. Hume explains this phenomenon through appeal to another 'seemingly trivial quality' of the imagination' – the unnatural ascent to higher levels of reflection strains the mind and prevents the successive reflexive reasonings from having their usual effects. When he first considers the question of reason's reflexive subversion of belief, he dismisses the question of whether he is himself a total sceptic on the grounds that such scepticism cannot be maintained with any constancy, and instead takes the argument as confirmation for his theory that belief consists in vivacity – for this best explains how the trivial quality of the imagination prevents the annihilation of belief.

Nevertheless, the conclusion that causal reasoning would, unless prevented by a seemingly trivial feature of the imagination, naturally annihilate all belief is unquestionably a disturbing one; and Hume returns to it, at the conclusion of his recital of sceptical considerations near the end of Book 1, in order to formulate what he calls a 'dangerous dilemma'. The dilemma is this: if we reject the trivial quality of the imagination that saves reason from its own reflexive self-subversion, then we must allow that all belief should be rejected; yet if we

accept the trivial quality of the imagination by making it a principle to reject all 'refined and elaborate arguments', we cut off much of science (which also depends on elaborate arguments); we must, on grounds of parity, accept all other features of the imagination as well, even those that clearly lead to illusion; and we contradict ourselves, for the argument supporting the need to reject refined and elaborate arguments is itself a refined and elaborate argument. The immediate result of this dilemma, Hume reports, is a state of intense and general doubt.

This intense general doubt constitutes a 'philosophical melancholy and delirium' that cannot be removed by argument but is naturally unsustainable. It is naturally succeeded, Hume reports, by a mood of 'indolence and spleen', in which an irresistible return to belief and reasoning concerning matters of ordinary life is combined with a disposition to avoid philosophizing, which has resulted in such discomfort. He thus finds himself operating in accordance with the principle (sometimes now called the *Title Principle*): 'Where reason is lively and mixes itself with some propensity, it ought to be assented to. Where it does not, it can have no title to operate on us'. Yet the state of indolence and spleen itself proves, in turn, to be unstable. For Hume finds naturally arising within him a renewed curiosity concerning philosophical topics and an ambition to contribute to the instruction of mankind and make a name for himself by his discoveries; and his return to philosophy is confirmed by the reflection that philosophy is a safer guide to speculation than is religion. He thus finds that the Title Principle, although originating in indolence and spleen, actually supports philosophical enquiry. Indeed, it avoids the 'dangerous dilemma' and provides a principle of belief that he can normatively endorse. For it allows him to discount the 'unlively' reasoning of the indefinitely iterated probability of causes that would gradually eradicate belief while nevertheless accepting 'refined and elaborate arguments' on topics of interest to him (arguments which thereby 'mix with some propensity'). His continuing awareness of the 'infirmities' of human cognitive nature that he has discovered produce a spirit of moderate scepticism – a 'diffidence' in judgment – but he regards those infirmities themselves with diffidence and endorses assent to his faculties (as corrected by reflection), ready to continue the investigations of his science of man into the passions and morals.

At the conclusion of the first *Enquiry*, Hume distinguishes between *antecedent scepticism* and *consequent scepticism*. Antecedent scepticism, which he identifies with the methodological scepticism of Descartes, is scepticism that occurs prior to the investigation of our faculties. It recommends beginning enquiry with universal doubt, even concerning the use of one's faculties, until those faculties have been validated by reasoning from a principle that cannot possibly be fallacious. Hume rejects this kind of scepticism on the grounds that no one self-evident principle is more certain than others and that no reasoning from such a principle could take place except by means of the very faculties that are supposed to be in doubt. (He does, however, endorse a more moderate antecedent scepticism consisting simply in antecedent caution and impartiality.) Consequent scepticism, in contrast, is scepticism that arises from the results of an investigation of our faculties, and Hume's own scepticism is of this kind. The results that he cites concern *the senses*, *abstract* (that is, demonstrative) *reasoning* and *moral evidence* (that is, probable reasoning). The consideration of sensory errors and illusions, he remarks, is a 'trite' topic of scepticism, and shows only that the first appearances of the senses often stand in need of correction. A more 'profound' sceptical consideration is a feature of the belief in bodies previously explained in the *Treatise*: namely, that the original version of this belief, identifying impressions themselves as continued and distinct existences, can be shown to be false, while the theory postulating that bodies are the causes of sensory impressions cannot be supported by causal reasoning based on observed constant conjunction. A further 'profound' topic, also presented in the *Treatise*, lies in the 'contradiction' between causal reasoning and the belief in bodies that arises from 'the modern philosophy'. The consideration concerning abstract reasoning lies in mathematical demonstrations of the infinite divisibility of extension, which Hume regards as paradoxical. (He refers in a footnote to the theory of extension he had proposed in the *Treatise*, according to which finite extensions are composed of finite numbers of unextended minima, as capable of resolving this paradox.) A 'popular' objection to moral or probable reasoning lies in the vast diversity of opinions among humankind. A more 'philosophical' objection, however, lies in the recognition that we have no argument to convince us that what we have observed to be constantly conjoined in our experience will continue to be so conjoined; only a natural instinct that leads us to make this supposition. The *Enquiry* omits discussion of reasoning's reflexive annihilation of belief, and hence also of the 'dangerous dilemma' that it posed. Nor is there any mention of the Title Principle, of the stage of 'indolence and spleen' that gave rise to it, or the role of curiosity and ambition in motivating a return to philosophy. There is, however, a distinction between 'Pyrrhonian' or 'excessive' scepticism, on

the one hand, and 'Academic' or 'mitigated' scepticism on the other. Intense contemplation of sceptical considerations naturally produces a 'tincture' of Pyrrhonian scepticism that is useful in moderating dogmatic self-confidence. Were Pyrrhonian doubt to remain constant, however, it would destroy human life by preventing action. Fortunately, however, the sources of belief in human nature are too powerful to allow this to occur, and the natural outcome of reflection on sceptical considerations is a more durable Academic scepticism that consists in a certain diffidence, modesty and lack of dogmatism in all one's judgments plus a determination to refrain from all 'high and distant enquiries' beyond our faculties – such as cosmological speculation concerning 'the origins of worlds' – that have no connection to 'common life'. Hume in the *Enquiry* recommends and endorses this mitigated scepticism, which he judges to be socially useful, he with a rousing call for the elimination of scholastic metaphysics and theology not based on mathematical or experimental reasoning : 'Commit it then to the flames: for it can contain nothing but sophistry and illusion'.

In order to characterize Hume's scepticism, it is useful to distinguish several different dimensions in which scepticism can vary. One of these is its *scope* – that is, the range of propositions to which it applies. Another is its *character* – that is, whether it consists in actual doubt, in a normative injunction to doubt, in a theoretical claim that a proposition lacks support through reasoning, or in a claim that a proposition lacks epistemic merit. A third is its *degree* – that is, whether it is unmitigated or mitigated. A fourth is its *basis* – that is, whether it is antecedent to enquiry or consequent to it. A fifth is its *constancy* – that is, whether it is constant or variable. In these terms, all of Hume's scepticism appears to be consequent to enquiry. He both engages in and recommends a mitigated doubt concerning all topics, as well as unmitigated doubt concerning 'high and distant' enquiries. The actual doubt in which he engages with respect to other topics is somewhat variable – potentially unmitigated in rare moments when intensely considering sceptical topics, and sometimes entirely absent in moments of special conviction. He unmitigatedly rejects the claim that the uniformity of nature and the belief in bodies *originate* with support through reasoning. But he is not committed to the view that only propositions produced or supported by reasoning have epistemic merit. On the contrary, as his endorsement of the Title Principle and his preference for 'wise' beliefs over unphilosophical probability indicate, his mitigated scepticism about the epistemic merit of beliefs generally allows him to hold that many beliefs have some degree of epistemic merit.

10 Motivation

Philosophers from PLATO to Spinoza have recommended actions motivated by reason rather than passion. Hume argues, however, that just as reason cannot produce the key transition in probable inference or the belief in an external world of bodies, so too reason alone cannot determine the will to act. His primary argument (THN 2.3.3) is as follows. All reasoning is either demonstrative or probable. Because demonstrative reasoning discovers only relations of ideas – primarily mathematical relations – and does not discover the actual existence or non-existence of things, it cannot motivate any action directly, but affects action only by facilitating the mathematical formulation and application of causal generalizations. Probable reasoning, which discovers causal relations themselves through experience, can serve to direct action by showing the means to a desired end, but cannot alone motivate it. For as long as objects do not affect one's passions (including desire and aversion), the will remains indifferent to their causal relations. Furthermore, since reason could oppose an operation of the will only by providing a contrary motivation, reason can never oppose passion in the direction of the will. Hence, Hume declares, 'reason is, and ought only to be, the slave of the passions, and can never pretend to any other office than to serve and obey them'.

In further support of this conclusion, Hume argues that passions are 'original existences' lacking any representative quality, and hence cannot be opposed to the claims to truth produced by reasoning. Reason can never oppose a passion, but only a judgment accompanying a passion. Where a passion concerns an object judged to exist but which does not really exist, or where action takes particular form due to a false belief that something stands as a causal means to a desired end, the passion itself may be called 'unreasonable', but only in an improper sense, for it is the accompanying judgment that is unreasonable. The appearance that reason and passion can struggle for the determination of the will results largely from the existence of 'calm passions' – such as the general appetite to pleasure and aversion to evil as such – that feel, in their operation, much like the calm operations of reason.

Hume is sometimes characterized as holding a limited conception of 'practical reason': namely, that passions determine one's ends, and that the only form of practical reasoning is the generation of new desires or actions from given ends and beliefs about

the means to those ends. On this view, then, one acts irrationally only when one fails to pursue the means to one's ends. In fact, however, Hume rejects even this limited conception. For him, the outcome of reasoning itself is belief, not desire or action; and although reasoning can, in concert with other aspects of one's nature, contribute to the production of new desires and actions, this process of production is not itself one of reasoning. While Hume regards failing to take the acknowledged means to one's ends as folly and subject to criticism, therefore, it is only in an improper sense 'irrational'.

11 The foundations of morality

Many of Hume's predecessors – like his successor KANT and many others – held that moral distinctions are made by reason. According to Clarke, for example, morality was a matter of relations of 'fittingness' that could be discerned and demonstrated, like geometrical relations, through reason. Hume denies that moral distinctions are derived from reason alone. For this, he offers three arguments in the *Treatise* (THN 3.1.1). The first argument concerns the non-representational character of the objects of moral evaluation. Reason is a kind of discovery of truth or falsehood, which is a relation of agreement or disagreement that ideas have either to other ideas or to 'real existence and matters of fact'. Because passions, volitions and actions are non-representational, however, they are not subject to such agreement or disagreement, and hence cannot be either contrary or conformable to reason. The second argument concerns the motivational force of moral distinctions. Since morals have an immediate influence on action and affections, while reason alone has already been shown to have no such influence, Hume argues, it follows that morals cannot be derived from reason alone. The third argument involves Hume's familiar strategy of surveying the kinds of reasoning. Moral distinctions cannot be derived from demonstrative reason, he claims, since all demonstrative reasoning depends on four of the philosophical relations of ideas – resemblance, contrariety, degrees of a quality, or proportion in quantity or number. If there is some further relation that can serve as a basis for the drawing of moral distinctions by demonstration alone, it must first be discovered; and, furthermore, it must be shown both how it can be limited to the relations between the mind and external objects (as morality is) and how it can provide motivation to any being capable of demonstrative reasoning (since morality is inherently motivating). Yet moral distinctions also cannot be derived from probable reasoning, for the virtue or vice of an action does not appear merely upon reasoning concerning matters of fact about the action; rather, it becomes apparent only upon turning one's attention to one's own sentiments.

Hume's investigation of the causal basis of the key transition in probable inferences yields first a negative answer – 'not reason' – and then a positive answer: 'custom or habit'. So, too, his investigation of the origin of moral distinctions yields first a negative answer – 'not reason alone' – and a positive answer. The positive answer, in this case, is 'a moral sense'. The moral sense consists in the capacity to feel specific sentiments of moral approbation and moral disapprobation when considering a person's character 'in general' – that is, as it affects persons considered generally, independently of one's own self-interest.

In some cases, a trait may produce approbation or disapprobation immediately, but typically it does so through *sympathy* with those who are affected by it – either its possessor or others, or both. Sympathy is, like probable inference, a mechanism by which perceptions are enlivened. In sympathy, however, one infers from circumstances or behaviour the feelings and sentiments of others, and this lively idea constituting belief that another person has a given feeling or sentiment is further enlivened by the current impression of oneself, as a result of the associative relation of resemblance between one's idea of the other person and one's idea or impression of oneself. The result is that the belief itself rises to the level of an impression, so that one sympathetically feels the other person's inferred state of mind oneself. Thus, when an individual has a character trait that produces pleasure for the individual or for others affected by that individual, an observer feels sympathetic pleasure, which then causes in the observer the further pleasant sentiment of moral approbation; when an individual has a feature of character that produces pain for the individual or others affected by that individual, the observer feels sympathetic pain, which then causes the further unpleasant sentiment of moral disapprobation.

As these sentiments give rise to abstract ideas, features of character producing moral approbation come to be called 'virtues' and those producing moral disapprobation come to be called 'vices'. Actions, in turn, are considered virtuous or vicious in so far as they are manifestations of virtuous or vicious character traits. Accordingly, Hume offers two definitions of 'virtue' or 'personal merit' parallel to his two definitions of 'cause': virtue is 'every quality of the mind, which is useful or agreeable to the person himself or to others' (EPM 9.12) or 'whatever mental quality gives to a spectator the pleasing sentiment of approbation' (EPM Appendix 1.11). Actual moral sentiments

may vary with the strength of one's sympathy, itself partly a function of one's distance, in various respects, from the individual evaluated and to those affected by the individual. In order to reconcile differences of sentiment among individuals and within the same individual at different times, we naturally come to 'correct' for peculiarities of perspective, much as we correct our judgments of sensory and aesthetic qualities. In the case of moral qualities, we do so by taking up imaginatively a 'general point of view' as the proper perspective from which to make moral judgments.

In claiming that moral distinctions are derived from a moral sense and not from reason alone, Hume is not denying that reasoning plays an essential role in the drawing of moral distinctions. Reasoning is required to determine the character traits of others, and reasoning is required in order to determine the likely effects of those traits on the possessor and others. Reasoning may also be required to determine what one's sentiments would be from 'the general point of view' when one is not actually occupying it. Although he is often interpreted as an expressivist non-cognitivist in ethics – that is, as holding that moral judgments express sentiments and are not strictly susceptible of truth or falsehood, his account of the 'correction' of moral sentiments through the 'general point of view' in the construction of abstract ideas of vice and virtue leaves room for a cognitivist interpretation as well, making the moral sense more closely analogous to senses for other qualities.

For Hume, as for ancient virtue ethicists, the primary object of evaluation is personal character, rather than actions, and the primary terms of moral evaluation are 'virtuous' and 'vicious', rather than 'right' and 'wrong' or 'good' and 'bad'. Because he maintains that moral distinctions depend on sentiment rather than on reason alone, Hume rejects the ideal of a morality that would have to be accepted by any rational being; and, indeed, he emphasizes that there is no reason to suppose that an intelligent deity would have the same moral sense as human beings. Morality, for Hume, is inherently motivating, to those who have a moral sense, because the moral sentiments themselves are pleasures and pains, and, as such, they also readily give rise to pride or love (which are further pleasures) and humility or hatred (which are further pains). He fully approves of morality, for the moral sense bestows approbation both on the having of a moral sense and on its own operations. At the same time, however, he treats morality as a natural phenomenon to be understood by the science of man. Indeed, he holds that by understanding the basis of morality in human nature, one is better equipped to reflectively improve one's moral evaluations (recognizing, for example, that the 'monkish virtues' such as celibacy, fasting, mortification and self-denial are not truly virtues) and to recommend morality more persuasively to others.

12 Political obligation

In his *Second Treatise of Government*, Locke grounds the political obligation to obey and sustain one's government in a social contract, a mutual promise by which individuals pool some of their natural rights in a civil society in order to better protect their property. The obligation to keep promises and to respect property, in turn, together with the basic rules that determine the acquisition of property, are features of Natural Law. While sympathetic to Locke's aim of justifying resistance to tyrannical governments that fail to protect citizens and their property, Hume offers accounts of the political obligation to obey and sustain government (which he calls *allegiance*), the obligation to respect property (which he calls *justice*), the obligation to keep promises (which he calls *fidelity*) and the relations among them, that are very different from Locke's.

Hume distinguishes *artificial virtues*, which depend on artifice and convention, from *natural virtues* (such as benevolence, cheerfulness, prudence and industry), which do not (THN 3.2). A 'convention' between two or more individuals does not demand an explicit promise; rather, it requires a presumed sense of common interest in a coordinated course of action, and an expressed and mutually understood determination to act in accordance with that coordinated course of action on the condition that others will do so as well. Rights to property and the rules that govern its acquisition are not inscribed in a pre-conventional law of nature, but rather arise as the result of a convention to protect the stability of actual possession (that is, control of goods), a convention that is originally motivated by the self-interest of all those involved. Recognition of the usefulness to the general public of the character trait of abiding by the rules of property, however, and sympathy with all those who benefit from it, causes the trait to be recognized as a virtue (THN 3.2.2). Promise making, too, arises as the result of a convention motivated by self-interest, one that allows the coordination of non-simultaneous exchanges of benefits by instituting a form of words that commits one to perform future benefits on pain of subsequent exclusion from the valuable convention in the event of non-compliance. The character trait of promise keeping, like that of obedience to the rules of property, comes to be approved as a virtue through sympathy with the broad range of those benefiting from the trait (THN 3.2.5).

The need for conventions of property and promise keeping in order to provide stable possession and mutual exchange of benefits, respectively, will lead to their invention and institution even within individual families and very small societies, Hume holds. In such circumstances, violators are, for the most part, easily detected and effectively sanctioned. Governments arise – often beginning with deference to a chieftain who has been a leader during war-time – as a convention to maintain the rules of property and promise keeping in larger societies by making it directly in the interests of some individuals to enforce those rules impartially. The convention of deferring to a chieftain for governance may indeed often originate in a promise among the members of a society. However, the obligation of citizens to allegiance is grounded, Hume argues, not in any original promise of the founders of government, nor (as Locke allowed) in a 'tacit' promise or consent on the part of current citizens, but rather on the general utility of allegiance, which gives rise to sympathetic pleasure and hence moral approbation (THN 3.2.7-8). Justice, fidelity and allegiance are all artificial virtues, each depending for its existence on a distinct convention, and the virtuousness or moral obligation of each has a similar but distinct basis in social utility. The obligation to allegiance stands on its own, and need not be derived from other obligations that themselves have a similar basis. Where a government becomes so tyrannical that it ceases to provide security and other benefits to its citizens, Hume allows, the moral obligation to obey and sustain the government naturally ceases. Although he has a lively sense – evident in his *History of England* – of the dangers of anarchy and the preferability of even quite imperfect governors to it, he is also a staunch defender of the importance to a society of free thought and expression.

13 Hume's legacy

Every philosophical generation since Hume has been obliged to understand itself in relation to his philosophy. Scottish common-sense philosophers (see COMMON SENSE SCHOOL) such as Thomas REID read it as a demonstration that Locke's 'way of ideas', according to which we can be directly aware only of the contents of our own minds, led inevitably to scepticism and must be rejected. Kant famously proclaimed that he had been 'awakened from his dogmatic slumbers' by the challenge of Hume's treatment of the concept of causation and took his own transcendental idealism to be the only way to avoid Humean scepticism. Utilitarians took inspiration from his emphasis on the essential relation of morality to what is useful and agreeable. British Idealists such as T.H. GREEN and F.H. BRADLEY took Hume to be a prime example of the dangers of an atomistic and sensation-based account of the capacities of mind. The logical positivists of the early twentieth century saw Hume's concern to trace the content of concepts to their experiential basis as a precursor of their own methodology – which they regarded as properly purged of Hume's conflation of philosophy and psychology. To broadly empiricist and naturalistic philosophers of the present era, Hume's philosophy is a powerful example of the effort to integrate the scientific understanding of human cognitive and conative nature into the scientific understanding of nature itself, to account for the normativity of reason and morals within the structure of that understanding, and to turn that understanding on to the understanding of philosophizing itself. Now widely regarded as the greatest philosopher to write in English, perhaps no philosopher of the early modern period has proven to be of greater relevance or importance to contemporary philosophy than Hume. The best evidence of this is the number of topics – from concepts to causation, from induction to the emotions, from scepticism to free will, from theology to practical reason, from morality to politics – on which a 'Humean' approach is one of the primary live options.

HUMOUR

What is meant by saying that something is humorous or funny? It is clear that humorousness must be elucidated in terms of the characteristic response to humour, namely humorous amusement, or mirth. It is plausible to define humour in this way: for something to be humorous is for it to be disposed to elicit mirth in appropriate people through their awareness or cognition of it, and

not for ulterior reasons. But this invites the question, 'What is mirth?' The three leading ideas in philosophical theories of humour are those of incongruity, superiority and relief or release. Although the perception of incongruity is often involved in finding something funny, and the resolution of a perceived incongruity plays an important role in good humour, none of these, in themselves or combined with others, is capable of capturing the concept of mirth. Mirth is not identical with the pleasurable perception of an incongruity, pleasure in feeling superior, the relief of tension or release of accumulated mental energy, or any combination of these elements. A better account of mirth is that it is a certain kind of pleasurable reaction which tends to issue in laughter if the reaction is sufficiently intense. So something is funny if it in itself pleases appropriate people through being grasped, where the pleasure is of the sort that leads, though not inevitably, to laughter.

JERROLD LEVINSON

HUS, JAN (*c.*1369–1415)

From his appointment as rector of the Bethlehem chapel in Prague in 1402 until his execution at the Council of Constance in 1415, Jan Hus advanced the goals of an ecclesiastical reform movement with Czech national overtones. Hus' ministerial and academic posts provided a broad platform for his leadership. He preached tenaciously against clerical abuses. At the University of Prague he taught philosophical and ecclesiological doctrines which, his opponents charged, were taken from the radical Oxford reformer, John Wyclif. Whereas Wyclif's philosophical realism (for example, the indestructibility of 'being') led him to adopt several positions condemned as heretical, Hus' polemic, in which he castigated the fiscalization and bureaucratization of the papacy, sprang more from his ideals of evangelical minority and apostolic poverty.

CURTIS V. BOSTICK

HUSSERL, EDMUND (1859–1938)

Introduction

Through his creation of phenomenology, Edmund Husserl was one of the most influential philosophers of our century. He was decisive for most of contemporary continental philosophy, and he anticipated many issues and views in the recent philosophy of mind and cognitive science. However, his works were not reader-friendly, and he is more talked about than read.

Husserl was born in Moravia, received a Ph.D. in mathematics while working with Weierstraß, and then turned to philosophy under the influence of Franz Brentano. He was particularly engaged by Brentano's view on intentionality and developed it further into what was to become phenomenology. His first phenomenological work was *Logische Untersuchungen* (Logical Investigations) (1900–1). It was followed by *Ideen* (Ideas) (1913), which is the first work to give a full and systematic presentation of phenomenology. Husserl's later works, notably *Vorlesungen zur Phänomenologie des inneren Zeitbewusstseins* (On the Phenomenology of the Consciousness of Internal Time) (1928), *Formale und transzendentale Logik* (Formal and Transcendental Logic) (1929), *Kartesianische Meditationen* (Cartesian Meditations) (1931) and *Krisis der europäischen Wissenschaften und die transzendentale Phänomenologie* (Crisis of the European Sciences) (partly published in 1936), remain largely within the framework of the *Ideas*. They take up topics that Husserl only dealt with briefly or were not even mentioned in the *Ideas*, such as the status of the subject, intersubjectivity, time and the lifeworld.

Brentano had characterized intentionality as a special kind of directedness upon an object. This leads to difficulties in cases of hallucination and serious misperception, where there is no object. Also, it leaves open the question of what the directedness of consciousness consists in. Husserl therefore endeavours to give a detailed analysis of those features of consciousness that make it as if of an object. The collection of all these features Husserl calls the act's 'noema'. The noema unifies the consciousness we have at a certain time into an act that is seemingly directed towards an object. The noema is hence not the object that the act is directed towards, but is the structure that makes our consciousness be as if of such an object.

The noemata are akin to Frege's 'third world' objects, that is, the meanings of linguistic expressions. According to Husserl, 'the noema is nothing but a generalization of the notion of meaning [Bedeutung] to the field of all acts' (*Ideas* 1913). Just as distinguishing between an expression's meaning and its reference enables one to account for the meaningful use of expressions that fail to refer, so, according to Husserl, can the distinction between an act's noema and its object help us overcome Brentano's problem of acts without an object.

In an act of perception the noema we can have is restricted by what goes on at our sensory surfaces,

but this constraint does not narrow our possibilities down to just one. Thus in a given situation I may perceive a man, but later come to see that it was a mannequin, with a corresponding shift of noema. Such a shift of noema is always possible, corresponding to the fact that perception is always fallible. These boundary conditions, which constrain the noemata we can have, Husserl calls 'hyle'. The hyle are not objects experienced by us, but are experiences of a kind which we typically have when our sense organs are affected, but also can have in other cases, for example under the influence of fever or drugs.

In our natural attitude we are absorbed in physical objects and events and in their general features, such as their colour and shape. These general features, which can be shared by several objects, Husserl calls essences, or 'eidos' (*Wesen*). Essences are studied in the eidetic sciences, of which mathematics is the most highly developed. We get to them by turning our attention away from the concrete individuals and focusing on what they have in common. This change of attention Husserl calls 'the eidetic reduction', since it leads us to the eidos. However, we may also more radically leave the natural attitude altogether, put the objects we were concerned with there in brackets and instead reflect on our own consciousness and its structures. This reflection Husserl calls 'the transcendental reduction', or 'epoché'. Husserl uses the label 'the phenomenological reduction' for a combination of the eidetic and the transcendental reduction. This leads us to the phenomena studied in phenomenology, that is, primarily, the noemata.

The noemata are rich objects, with an inexhaustible pattern of components. The noema of an act contains constituents corresponding to all the features, perceived and unperceived, that we attribute to the object, and moreover constituents corresponding to features that we rarely think about and are normally not aware of, features that are often due to our culture. All these latter features Husserl calls the 'horizon' of the act. The noema is influenced by our living together with other subjects where we mutually adapt to one another and come to conceive the world as a common world in which we all live, but experience from different perspectives. This adaptation, through empathy (*Einfühlung*), was extensively studied by Husserl.

Husserl emphasizes that our perspectives and anticipations are not predominantly factual: 'this world is there for me not only as a world of mere things, but also with the same immediacy as a world of values, a world of goods, a practical world' (*Ideas* 1913). Further, the anticipations are not merely beliefs – about factual properties, value properties and functional features – but they also involve our bodily habits and skills.

The world in which we find ourselves living, with its open horizon of objects, values, and other features, Husserl calls the 'lifeworld'. It was the main theme of his last major work, *The Crisis of the European Sciences*, of which a part was published in 1936. The lifeworld plays an important role in his view on justification, which anticipates ideas of Goodman and Rawls.

1 Life

Edmund Gustav Albrecht Husserl was born of Jewish parents in Prossnitz (now Prostejov in the Czech Republic) in Moravia, in what was then Austria-Hungary on 8 April 1859. He was thus of the same age as Dewey and Bergson.

Husserl's early interests lay in the direction of mathematics and science. In 1876 he began studying mathematics and astronomy at the University of Leipzig. After three semesters he transferred to the University of Berlin in order to study with Weierstraß, Kronecker and Kummer, a trio that made Berlin a centre in the mathematical world during that period. After three years in Berlin he left for Vienna, where he received his doctorate in January 1883. He then returned to Berlin in order to become an assistant for Weierstraß. However, Weierstraß became ill, and after just one semester in Berlin Husserl entered military service for a year, spending most of it in Vienna. A growing interest in religious questions made him decide in 1884 to study philosophy with Franz Brentano in Vienna, who inspired him to go into philosophy full-time and exerted a decisive influence on his later phenomenology.

Husserl studied with Brentano until 1886, when Brentano advised him to go to Halle, where one of Brentano's earlier students, Carl Stumpf, was teaching philosophy and psychology. Husserl habilitated

in Halle in 1887 and remained there as a *Privatdozent* until 1901, when he became Associate Professor (*außerordentlicher Professor*) in Göttingen, and in 1906 Full Professor. In 1916 he went to Freiburg, where he taught until he retired in 1928. He died in Freiburg on 27 April 1938.

Husserl's first philosophical work was his Habilitation dissertation, *On the Concept of Number*, which was printed, but not published, in 1887. This was incorporated into the first three chapters of his *Philosophy of Arithmetic*, whose first volume was published in 1891. A second volume was announced, but never came. Instead, Husserl underwent a radical philosophical reorientation. He gave up his main project in *Philosophy of Arithmetic*, which had been to base mathematics on psychology. Instead, he developed his lasting philosophical achievement, phenomenology, which was first presented in *Logische Untersuchungen* (Logical Investigations), arriving in two volumes in 1900 and 1901. In 1905–7 he introduced the idea of a transcendental reduction and gave phenomenology a turn towards transcendental idealism. This new version of phenomenology was expounded in *Ideen* (Ideas) (1913), and is the most systematic presentation of phenomenology.

Husserl's notable later works were *Vorlesungen zur Phänomenologie des inneren Zeitbewusstseins* (On the Phenomenology of the Consciousness of Internal Time) (1928), *Formale und transzendentale Logik* (Formal and Transcendental Logic) (1929), which Husserl characterized as his most mature work, and *Kartesianische Meditationen* (Cartesian Meditations) (1931). The first part of his *Krisis der europäischen Wissenschaften* (Crisis of the European Sciences) was published in 1936, but the main part of this work and about 40,000 pages of manuscripts were left after his death. These manuscripts, together with Husserl's family and his library, were rescued from Germany by the Belgian Franciscan Van Breda, who established the Husserl Archive in Louvain, where the material is now accessible to researchers. Copies of the manuscripts are kept in other Husserl archives in various parts of the world. Gradually, the most important parts of Husserl's papers and scholarly editions of his published works are being published in the series *Husserliana*. In addition, *Erfahrung und Urteil* (Experience and Judgment) was prepared by Husserl's assistant Ludwig Landgrebe in consultation with Husserl, and appeared shortly after Husserl's death in 1938. Husserl's main works are available in good English translations.

2 Intentionality

The central theme of phenomenology is intentionality. All of phenomenology can be regarded as an unfolding of the idea of intentionality (see Intentionality). Husserl's interest in intentionality was inspired by his teacher, Franz Brentano. However, there are many differences between Husserl's treatment of this notion and that of Brentano. This section deals first with these differences, then goes on to further features of Husserl's notion of intentionality reaching beyond the issues considered by Brentano.

Husserl retains the following basic idea of Brentano's: 'We understand by intentionality the peculiarity of experiences to be "consciousness of something"' (*Ideas* 1913; Husserl's emphasis). Husserl's formulation comes close to Brentano's oft-quoted passage from *Psychology from an Empirical Point of View*:

> Every mental phenomenon is characterized by what the scholastics in the Middle Ages called the intentional (and also mental) inexistence of an object, and what we could also call, although in not entirely unambiguous terms, the reference to a content, a direction upon an object.

However, there is already an important difference between Brentano and Husserl at this starting-point. While Brentano says straightforwardly that for every act there is an object towards which it is directed, Husserl focuses on the 'of'-ness of the act. There are two reasons for this difference: First, Husserl wants to get around the difficulties connected with acts that lack an object. Second, he aims to throw light on what it means for an act to be 'of' or 'about' something. Let us begin by discussing these two differences.

Acts that lack an object. Brentano's thesis may seem unproblematic in the examples Brentano considered: just as when we love there is somebody or something that we love, so there is something that we sense when we sense, something we think of when we think, and so on. However, what is the object of our consciousness when we hallucinate, or when we think of a centaur? Brentano insisted that even in such cases our mental activity, our sensing or thinking, is directed towards some object. The directedness has nothing to do with the reality of the object, he held. The object is contained in our mental activity, 'intentionally' contained in it. And Brentano defined mental phenomena as 'phenomena which contain an object intentionally'.

Not all of Brentano's students found this lucid or satisfactory, and the problem continued to disturb both them and Brentano. Brentano struggled with it for the rest of his life, and suggested, among other things, a translation theory, giving Leibniz credit for the idea: when we describe an act of hallucination, or of thinking of a centaur, we are only apparently

referring to an object. The apparent reference to an object can be translated away in such a way that in the full, unabbreviated description of the act there is no reference to any problematic object. There are two weaknesses of Brentano's proposal. First, unlike Russell later, Brentano does not specify in detail how the translation is to be carried out (see RUSSELL, B.). Second, if such a translation can be carried out in the case of hallucinations and so on, then why not carry it out everywhere, even in cases of normal perception? What then happens to the doctrine of intentionality as directedness upon an object?

One of Brentano's students, Alexius MEINONG, suggested a simple way out. In his *Gegenstandstheorie* Meinong maintained that there are two kinds of objects: those that exist and those that do not exist. Hallucinations, like normal perception, are directed towards objects, but these objects do not exist. Brentano was not happy with this proposal. He objected that, like Kant, he could not make sense of existence as a property that some objects have and others lack.

Husserl's solution was, as noted, to emphasize the 'of'. Consciousness is always consciousness *of* something. Or better, consciousness is always *as if of* an object. What matters is not whether or not there is an object, but what the features are of consciousness that makes it always be 'as if of' an object. These three words, 'as if of' are the key to Husserl's notion of intentionality. To account for the directedness of consciousness by saying only that it is directed towards an object leaves us in the dark with regard to what that directedness is. This leads us to the second reason for why Husserl diverged from Brentano. Husserl wanted to throw light on just this issue: what does the directedness of consciousness consists in? He made it a theme for a new discipline: the discipline of phenomenology.

What is directedness? To get a grip on what the directedness of consciousness consists in – to understand better the word 'of', which Husserl emphasized in his definition of intentionality quoted at the beginning of §2 above – let us note that for Husserl intentionality does not simply consist in consciousness directing itself towards objects that are already there. Intentionality for Husserl means that consciousness in a certain way 'brings it about' that there are objects. Consciousness 'constitutes' objects, Husserl said, borrowing a word from the German idealists, but using it in a different sense. Above, the phrase 'brings it about' was put in quotation marks to indicate that Husserl does not mean that we create or cause the world and its objects. 'Intentionality' means merely that the various components of our consciousness are interconnected in such a way that we have an experience as of one object. To quote Husserl:

> an object 'constitutes' itself – 'whether or not it is actual' – in certain concatenations of consciousness which in themselves bear a discernible unity in so far as they, by virtue of their essence, carry with themselves the consciousness of an identical X.
>
> (*Ideas*; translation emended)

Husserl's use, here and in many other places, of the reflexive form 'an object constitutes itself', reflects his view that he did not regard the object as being produced by consciousness. Husserl considered phenomenology as the first strictly scientific version of transcendental idealism, but he also held that phenomenology transcends the traditional distinction between idealism and realism, and in 1934 he wrote in a letter to Abbé Baudin: 'No ordinary "realist" has ever been as realistic and concrete as I, the phenomenological "idealist" (a word which by the way I no longer use)'. In the preface to the first English edition of the *Ideas* (1931), Husserl stated:

> Phenomenological idealism does not deny the factual [*wirklich*] existence of the real [*real*] world (and in the first instance nature) as if it deemed it an illusion.... Its only task and accomplishment is to clarify the sense [*Sinn*] of this world, just that sense in which we all regard it as really existing and as really valid. That the world exists...is quite indubitable. Another matter is to understand this indubitability which is the basis for life and science and clarify the basis for its claim.

To see more clearly what Husserl is after, consider Jastrow and Wittgenstein's duck/rabbit picture. In order to come closer to Husserl we should modify the example and consider not a picture, but a silhouette of the real animal against the sky. When we see such a silhouette against the sky, we may see a duck or a rabbit. What reaches our eyes is the same in both cases, so the difference must be something coming from us. We structure what we see, and we can do so in different ways. The impulses that reach us from the outside are insufficient to determine uniquely which object we experience; something more gets added.

3 Noema

The structure that makes up the directedness of consciousness, Husserl called the 'noema'. More accurately, the noema has two main components. First, the 'object meaning' that integrates the various constituents of our experience into experiences of the various features of *one* object, and

second, the 'thetic' component that differentiates acts of different kinds, for example, the act of perceiving an object from the act of remembering it or thinking about it. The thetic component is thereby crucial for the reality-character which we ascribe to the object.

Our consciousness structures what we experience (see KANT, I.). How it structures it depends on our previous experiences, the whole setting of our present experience and a number of other factors. If we had grown up surrounded by ducks, but had never heard of rabbits, we would have been more likely to see a duck when confronted with the duck/rabbit silhouette; the idea of a rabbit would not have occurred to us.

The structuring always takes place in such a way that the many different features of the object are experienced as connected with one another, as features of one and the same object. When, for example, we see a rabbit, we do not merely see a collection of coloured patches, various shades of brown spread out over our field of vision (incidentally, even seeing coloured patches involves intentionality, since a patch is also a kind of object, but a different kind of object from a rabbit). We see a rabbit, with a determinate shape and a determinate colour, with the ability to eat, jump and so on. It has a side that is turned towards us and one that is turned away from us. We do not see the other side from where we are, but we see something which has another side.

That seeing is intentional, or object-directed, means just this, that it is as if of an object: the near side of the object we have in front of us is regarded as a side of a thing, and the thing we see has other sides and features that are co-intended, in the sense that the thing is regarded as more than just this one side. The object meaning of the noema is the comprehensive system of determinations that gives unity to this manifold of features and makes them aspects of one and the same object.

It is important at this point to note that the various sides, appearances or perspectives of the object are constituted together with the object. There are no sides and perspectives floating around before we start perceiving, which are then synthesized into objects when intentionality sets in. There are no objects of any kind, whether they be physical objects, sides of objects, appearances of objects or perspectives of objects without intentionality. And intentionality does not work in steps. We do not start by constituting six sides and then synthesize these into a die; we constitute the die and the six sides of it in one step.

We should also note that when we experience a person, we do not experience a physical object, a body, and then infer that a person is there. We experience a fully fledged person, we are encountering somebody who structures the world, experiences it from their own perspective. Our noema is a noema of a person; no inference is involved. Seeing persons is no more mysterious than seeing physical objects, and no inference is involved in either case. When we see a physical object we do not see sense-data or the like and then infer that there is a physical object there, but our noema is the noema of a physical object. Similarly, when we see an action, what we see is a fully fledged action, not a bodily movement from which we infer that there is an action.

The word 'object' must hence be taken in a very broad sense. It comprises not only physical things, but also, as we have seen, animals, and likewise persons, events, actions and processes, and sides, aspects and appearances of such entities.

Essences. Husserl distinguishes between physical objects and processes, which are temporal and normally also spatial, and essences (*Wesen*) or eidos, which are features that the object can share with other objects, such as the triangularity of a triangle or the greenness of a tree. For Husserl, an object's essence is therefore not something unique to that object, as it is for many other philosophers. Mathematics is the most highly developed study of essences.

Noema and meaning. The features of the noema that we have mentioned, in particular the role it plays in the analysis of acts without objects and the way it accounts for the object-directedness of acts, make it natural to compare the noema to the meaning of linguistic expressions. This comparison and the ensuing way of reading Husserl has been contested. However, it is well supported by textual and systematic considerations, and it is now often regarded as the standard way of interpreting Husserl. One factor contributing to this has been Husserl's own statement, in *Ideas*, that 'the noema is nothing but a generalization of the notion of meaning (*Bedeutung*) to the field of all acts'.

Noesis. The noema is an abstract structure that can in principle be the same from act to act, in the unlikely case that at two different occasions we should have the same kind of experience of the same object from the same point of view, with exactly the same anticipations, and so on. An act has a noema in virtue of comprising a kind of experience that Husserl calls a 'noesis'. The noema is the meaning given in an act, Husserl says, while the noesis is the meaning-giving aspect of the act. There is hence a close parallelism between noema and noesis. The relation between noema and noesis bears some similarity to the type/token relation in Peirce (see TYPE/TOKEN DISTINCTION). The noesis is a temporal process, in which the noema 'dwells'.

4 Hyle; filling; evidence

In acts of perception, the noema that we can have is restricted by what goes on at our sensory surfaces, but the restriction does not narrow our possibilities down to just one. Thus in a given situation I may perceive a man, but later come to see that the man was a mannequin, with a corresponding shift of noema. Such a shift of noema is always possible, corresponding to the fact that perception is always fallible. These boundary conditions, which constrain the noemata we can have, Husserl calls 'hyle'. The hyle are not objects experienced by us, but are experiences of a kind which we typically have when our sense organs are affected, but also can have in other cases, for example, under the influence of fever or drugs.

In the case of an act of perception, its noema can also be characterized as a very complex set of expectations or anticipations concerning what kind of experiences we will have when we move around the object and perceive it, using our various senses. We anticipate different further experiences when we see a duck and when we see a rabbit. In the first case we anticipate, for example, that we will feel feathers when we touch the object, while in the latter case we expect to find fur. When we get the experiences we anticipate, the corresponding component of the noema is said to be 'filled'. In all perception there will be some filling: the components of the noema that correspond to what presently 'meets the eye' are filled, and similarly for the other senses.

Such anticipation and filling is what distinguishes perception from other modes of consciousness, such as imagination or remembering. If we merely imagine things, our noema can be of anything whatsoever. In perception, however, our sensory experiences are involved; the noema has to fit in with our sensory experiences. This eliminates a number of noemata which I could have had if I were just imagining. In your present situation you can probably not have a noema corresponding to the perception of an elephant. This does not reduce the number of perceptual noemata you can have just now to one, for example, of having a book in front of you.

It is a central point in Husserl's phenomenology that I can have a variety of different perceptual noemata that are compatible with the present impingements upon my sensory surfaces. In the duck/rabbit case this was obvious, for we could go back and forth at will between having the noema of a duck and having the noema of a rabbit. In most cases, however, we are not aware of this possibility. Only when something untoward happens, when I encounter a 'recalcitrant' experience that does not fit in with the anticipations in my noema, do I start seeing a different object from the one I thought I saw earlier. My noema 'explodes', to use Husserl's phrase, and I come to have a noema quite different from the previous one, with new anticipations. This is always possible, he says. Perception always involves anticipations that go beyond what presently 'meets the eye', and there is always a risk that we may go wrong, regardless of how confident and certain we might feel.

When some components of the noema are filled, we have 'evidence'. Evidence comes in degrees, depending on how much of the noema is filled. Husserl discusses two kinds of perfect evidence: 'adequate' evidence, where every component in the noema is filled, with no unfilled anticipations, and 'apodictic' evidence, where the negation of what seems to be the case is self-contradictory. After some vacillation Husserl ended up holding that we can never attain any of these kinds of perfect evidence – we are always fallible.

5 Intuition

Husserl uses the term 'intuition' (*Anschauung*) for any act where an object is experienced as 'given', that is, as really there. Earlier philosophers have used the word 'intuition' in a variety of ways, mostly about some sort of direct, non-inferential insight. Perception has usually been classified as a kind of intuition. A key issue in medieval philosophy as well as in rationalism and empiricism was whether there are other sorts of such insight. Kant defined 'intuition' as a representation which 'relates immediately to its object and is singular' (*Critique of Pure Reason* 1781/87: A320; B376–7). Bernard Bolzano developed this idea with great precision. For Husserl, an intuition is an act where we are constrained in how we constitute its objects, such as we typically are in perception, which is one of his two varieties of intuition. He calls the other variety 'essential insight' (*Wesensschau*). The object is here a general feature, an essence. For Husserl, as for Kant, intuition is a key kind of evidence in mathematics. This, then, is what Husserl means by the mysterious-sounding term '*Wesensschau*'. One might still claim that there is no such thing, but it is difficult to reject the notion once one agrees that the object of an act is underdetermined by what reaches our senses, and one accepts the correlated idea of intentionality.

6 The reductions; phenomenology

Husserl distinguishes between several so-called 'reductions'. First, there is the 'eidetic' reduction, which we perform each time we pass from focusing

on an individual physical object to focusing on one of its essences (eidos). This kind of reduction has been carried out in mathematics since its beginning, and Husserl conceived of other eidetic sciences in addition to mathematics. Second, a reduction that is distinctive for phenomenology is a special kind of reflection. Instead of focusing on the normal objects of our acts, be they physical objects, actions, persons or general features that many objects can have in common, we reflect on the structures of our own consciousness and study the noemata, the noeses or the hyle. The noemata, the noeses and the hyle have two important features: we are normally not aware of them, and they are a *sine qua non* for the appearance of a world. Entities with these two features are called 'transcendental'. The reduction that leads to them, where the ordinary objects are bracketed, is therefore called the 'transcendental' reduction. Husserl also calls it the 'epoché', using a word that the ancient sceptics used for refraining from taking a stand. We study the features of the act that make it seem to have an object and do not ask whether or not it actually has one. Husserl got the idea of the transcendental reduction in 1905. It marks the transition from the early phenomenology of the *Logical Investigations* to the 'idealist' phenomenology of the *Ideas* and later works.

The 'phenomenological' reduction, finally, is the combination of the eidetic reduction and the transcendental reduction. That is, it is a reduction that leads us from acts directed towards physical objects via acts directed towards essences to acts directed towards the noema, noesis and hyle of acts directed towards essences. Husserl sometimes takes the two steps in the inverse order, starting with a transcendental reduction and then focusing on the essential traits of the noema, noesis and hyle. The end product is not quite the same, but the phenomenological reduction can presumably be either.

Phenomenology is the study of the transcendental elements in our experience that are uncovered through the phenomenological reduction: the noema, the noesis and the hyle. In phenomenology, all these three elements are studied, with emphasis on the noematic/noetic structures. Husserl carried out detailed analyses of temporal structures and how they are constituted, in *On the Phenomenology of the Consciousness of Internal Time*, on the structures that are basic to logic and mathematics, in *Formal and Transcendental Logic* and *Experience and Judgment*, and on intersubjectivity and the processes whereby we come to constitute a common world, in *Cartesian Meditations* and in thousands of pages of manuscripts, the most important of which have been collected by Iso Kern in *Husserliana*, vols 13–15.

For Husserl, phenomenology is a study of the subjective perspective. In science one aims for objectivity and endeavours to arrange observations and experiments in such a way as to minimize differences between different observers. Phenomenology focuses on the subjective, on the manner in which each subject structures or 'constitutes' the world differently, on the basis of different experiences and cultural background, but also on the basis of adaptation to other subjects through interaction and communication.

7 The past

We constitute not only the different properties of things, but also the relation of the thing to other objects. If, for example, I see a tree, the tree is conceived of as something which is in front of me, as perhaps situated among other trees, as seen by other people than myself, and so on. It is also conceived of as something which has a history: it was there before I saw it, it will remain after I have left, or perhaps it will eventually be cut down and transported to some other place. However, like all material things, it does not simply disappear from the world.

My consciousness of the tree is in this way also a consciousness of the world in space and time in which the tree is located. My consciousness constitutes the tree, but at the same time it constitutes the world in which the tree and I are living. If my further experience makes me give up the belief that I have a tree ahead of me because, for example, I do not find a tree-like far side or because some of my other expectations prove false, this affects not only my conception of what there is, but also my conception of what has been and what will be. Thus in this case, not just the present, but also the past and the future are reconstituted by me. To illustrate how changes in my present perception lead me to reconstitute not just the present, but also the past, Husserl uses an example of a ball which I initially take to be red all over and spherical. As it turns, I discover that it is green on the other side and has a dent:

> the sense of the perception is not only changed in the momentary new stretch of perception; the noematic modification streams back in the form of a retroactive cancellation in the retentional sphere and modifies the production of sense stemming from earlier phases of the perception. The earlier apperception, which was attuned to the harmonious development of the 'red and uniformly round', is implicitly 'reinterpreted' to 'green on one side and dented'.
>
> (*Erfahrung und Urteil* 1938)

Husserl held that time and space are constituted. In *On the Phenomenology of the Consciousness of Internal Time* and various manuscripts that have been published in Volume 10 of *Husserliana* he gives a highly interesting analysis of the way objective time is constituted.

8 Values; practical function

So far we have focused on the factual properties of things. However, things also have *value* properties, and these properties are constituted in a corresponding manner. The world within which we live is experienced as a world in which certain things and actions have a positive value, others a negative. Our norms and values, like our beliefs, are subject to change. Changes in our views on matters of fact are often accompanied by changes in our evaluations.

Husserl emphasizes that our perspectives and anticipations are not predominantly factual. We are not living a purely theoretical life. According to Husserl, we encounter the world around us primarily 'in the attitude of the natural pursuit of life', as 'living functioning subjects involved in the circle of other functioning subjects'. Husserl says this in a manuscript from 1917, but he has similar ideas about the practical both earlier and later. Thus in the *Ideas* he says: 'this world is there for me not only as a world of mere things, but also with the same immediacy as a world of values, a world of goods, a practical world'.

In later manuscripts, particularly from 1917 onwards, Husserl focused more and more on the role of the practical and the body in our constitution of the world. Just as he never held that we first perceive sense-data, or perspectives or appearances, which are then synthesized into physical objects, or that we first perceive bodies and bodily movements and then infer that there are persons and actions, so it would be a grave misunderstanding of Husserl to attribute to him the view that we first perceive objects that have merely physical properties and then assign a value or a practical function to them. Things are directly experienced by us as having the features – functional and evaluational as well as factual – that are of concern for us in our natural pursuit of life.

In our discussion of the hyle we characterized the noema of an act of perception as a very complex set of expectations or anticipations concerning what kind of experiences we will have when we move around the object and perceive it. We should note that these experiences depend not only on our sensory organs, but also on the movements of our body, on our bodily skills and our familiarity with various kinds of practical activities. In numerous passages Husserl talks about practical anticipations and the role of kinesthesis in perception and bodily activity.

9 Horizon

When we are experiencing an object, our consciousness is focused on this object, and the rest of the world and its various objects are there in the background as something we 'believe in' but are not presently paying attention to. The same holds for most of the inexhaustibly many features of the object itself. All these further features of the object, together with the world in which it is set, make up what Husserl calls the 'horizon' of that experience. The various features of the object, which are co-intended, or also-meant, but not at the focus of our attention, Husserl calls the 'inner horizon', while the realm of other objects and the world to which they all belong, he calls the 'outer horizon'.

The horizon is of crucial importance for Husserl's concept of justification, which we shall discuss later. What is particularly significant is the hidden nature of the horizon. As we noted, the horizon is that which is not attended to. Take as an example our 'expectation' that we will find a floor when we enter a room. Usually, we have not even thought about there being a floor. Typically, we cannot even recall when we first acquired the corresponding 'belief' or 'anticipation'. According to Husserl, there may never have been any occasion when we actually judged there to be a floor in some particular room. Still we have come to 'anticipate' a floor, not in the sense of consciously expecting one, but in the sense that if we entered the room and there were none, we would be astonished. In this example we would easily be able to tell what was missing, in other cases our 'anticipations' are so imperceptible that we just may feel that something has gone awry, but not be able to tell what it is.

Words like 'belief' and 'anticipate' are clearly not the proper ones here, since they have overtones of something being conscious and thought about. Both English and German seem to lack words for what we want to get at here: Husserl uses the words '*antizipieren*', '*hinausmeinen*' and '*vorzeichnen*'.

10 Intersubjectivity

Throughout his life, Husserl emphasized that the world we intend and thereby constitute is not our own private world, but an intersubjective world, common to and accessible to all of us. Thus in the *Ideas* he writes:

> I continually find at hand as something confronting me a spatiotemporal reality [*Wirklichkeit*] to which I belong like all other human beings who are to be found in it and who are related to it as I am.

Husserl's studies of intersubjectivity focus in particular on the processes by which we experience others as experiencing subjects, like ourselves, and adapt our anticipations to those that we take them to have. Thanks to this, our way of constituting the world is not solipsistic, but we constitute the world as a shared world, which we each experience from our different perspective. A notion of objectivity arises, we may come to regard ourselves as deviant, for example, as colour-blind or as cognitively biased, and we also experience ourselves as confronted with a reality to which our beliefs and anticipations have to adapt. In works that remain largely unpublished, Husserl started to develop an ethics based in part on a study of the objectifying processes whereby objective ethical principles and norms arise from our subjective likes and dislikes.

Husserl stresses the shared, intersubjective nature of the world, particularly in §29 of the *Ideas*, which he entitles 'The "Other" Ego-subjects and the Intersubjective Natural Surrounding World'. There he says:

> I take their surrounding world and mine Objectively as one and the same world of which we are conscious, only in different ways [*Weise*]. . . . For all that, we come to an understanding with our fellow human beings and together with them posit an Objective spatiotemporal reality.

In the later works one finds similar ideas, particularly in the many texts that have been collected by Iso Kern in the three volumes of the *Husserliana* devoted to intersubjectivity, but also in many other works, for example in the *Crisis*:

> Thus in general the world exists not only for isolated men but for the community of men; and this is due to the fact that even what is straightforwardly perceptual is communal.

Husserl discusses in great detail empathy and the many other varieties of intersubjective adaptation that enable us to intend a common, intersubjective world. (See the three volumes on intersubjectivity referred to above.)

11 Existence

The passages quoted in §10 above express a further feature of Husserl's notion of intentionality which is rarely discussed, in spite of its importance: intentionality does not just involve directedness upon an object, but also a 'positing' of the object, corresponding to the two components of the noema discussed in §3 above. The object is experienced as real and present, as remembered, or as merely imagined, and so on. In the passages just quoted, Husserl said, 'I continually find at hand as something confronting me a spatiotemporal reality', and 'we come to an understanding with our fellow human beings and together with them posit an Objective spatiotemporal reality'. The same point is stressed also when he discusses the lifeworld in the *Crisis*:

> the lifeworld, for us who wakingly live in it, is always there, existing in advance for us, the 'ground' of all praxis, whether theoretical or extratheoretical. The world is pregiven to us, the waking, always somehow practically interested subjects, not occasionally but always and necessarily as the universal field of all actual and possible praxis, as horizon. To live is always to live-in-certainty-of-the-world.

Husserl discusses this *thetic* character of intentionality, and, correspondingly, of the noema, in many of his books and manuscripts. He was particularly concerned with what gives reality-character to the world. Like William James, whom he had read already when he made the transition to phenomenology in the mid-1890s, he stressed the importance of the body, and the inflictions upon our body, for our sense of reality. As James put it: 'Sensible vividness or pungency is then the vital factor in reality'(*The Principles of Psychology* 1890: 2, 301). Husserl could also have subscribed to James's observation that 'the *fons et origo* of all reality, whether from the absolute or the practical point of view, is thus subjective, is ourselves' (*Principles*: 2, 296–7).

This latter passage from James gets a double meaning in Husserl which expresses the core of his view of the reality of the world: the subjective (ourselves) is the *fons et origo* of all reality in two senses, a transcendental and an empirical: we constitute the world as real through our intentionality, and the reality-character we give it is derived from our being not merely transcendental subjects, but empirical subjects with a body immersed in a physical world.

12 The lifeworld

The idea of Husserl's that has become most widely known is that of the lifeworld. In particular, the word 'lifeworld' (*Lebenswelt*) itself has gained wide currency. It was used by Simmel and others before Husserl. After the Second World War it became a favourite word of many social scientists, who used it in many different senses. Several of them refer to Husserl without seeming to have studied his philosophy and therefore without knowing the many important features that the lifeworld has in his thought.

The first place Husserl uses the word 'lifeworld' in print is in his latest work, the *Crisis*, of which the first two parts were published in 1936. The rest of this unfinished work, containing the important third part, with the main discussion of the lifeworld, was not published until 1954, but it was known to some of Husserl's students and followers, including Maurice MERLEAU-PONTY, who came to the Husserl Archives in Louvain to study this part in April 1939.

Interpreters of Husserl differ widely in their views on the lifeworld. It is often thought that it constitutes a major break in Husserl's development, from the 'early' Husserl of the *Ideas* to the 'late' Husserl of the *Crisis*. Is it such a break? And second, what exactly is the lifeworld and what role does it play in phenomenology? On the former question the answer is a definite 'No'. The lifeworld is fully compatible with Husserl's earlier philosophy, and there is even a definite place for it in his phenomenology from its beginning. Husserl touches upon the lifeworld repeatedly in his earlier work and he gradually deepens and modifies his views on it, as he did with everything else in his phenomenology. Instead of regarding the life-world as a break with Husserl's earlier philosophy, we should view it as intimately connected with the other main themes in phenomenology. Properly to understand the lifeworld with all its nuances it is important to appreciate fully the connection between it and the rest of Husserl's philosophy.

The lifeworld arises from the distinction between the natural attitude and the transcendental or phenomenological attitude, which Husserl introduced in 1905. The first appearance of the notion for which he later introduced the term 'lifeworld' occurs shortly thereafter, in his lectures 'Fundamental Problems in Phenomenology' in 1910–11, that is, already before the *Ideas*. Husserl begins these lectures with an extended discussion of 'the natural attitude and the "natural world concept"'. Here he says:

> It could also be shown that philosophical interests of the highest dignity require a complete and comprehensive description of the so-called *natural world concept*, that of the natural attitude, on the other hand also that an accurate and profound description of this kind is not easily carried out, but on the contrary would require exceptionally difficult reflections.

Husserl here borrows the phrase 'natural world concept', which he emphasizes, from Richard Avenarius, whom he discusses later in the lecture. In a manuscript from 1915, Husserl describes this world in the following way (following Avenarius):

> All opinions, justified or unjustified, popular, superstitious, scientific, all relate to the already *pregiven world*. . . . All theory relates to this immediate givenness and can have a legitimate sense only when it forms thoughts which do not offend against the general sense of the immediately given. No theorizing may offend against this sense.

In the following years, Husserl repeatedly returns to this and related themes, using various labels that sometimes allude to other philosophers who had propounded similar ideas, such as Nietzsche. Quite often he uses Avenarius' phrase 'natural world'. In a manuscript from 1917, which appears to be the first place where he uses the word 'lifeworld', he introduces this new word as equivalent to the former: 'The lifeworld is the natural world – in the attitude of the natural pursuit of life are we living functioning subjects involved in the circle of other functioning subjects' (the manuscript dates from 1917, but was copied during the first half of the 1920s, and it is possible that the word 'lifeworld' appeared then).

Gradually during the 1920s and especially in the 1930s the lifeworld becomes a central theme in Husserl's writings, until his discussion culminates in the *Crisis* in 1936. One aim of this work was to provide a new and better access to phenomenology, through the notion of the lifeworld. The lifeworld is for Husserl our natural world, the world we live in and are absorbed by in our everyday activities. A main aim of phenomenology is to make us reflect on this world and make us see how it is constituted by us. Through the phenomenological reduction phenomenology will take us out of our natural attitude where we are absorbed by the world around us, into the phenomenological, transcendental attitude, where we focus on the noemata of our acts – on our structuring of reality.

Pregivenness. In the passage just quoted from Husserl's 1915 manuscript, Husserl says that the world is pregiven (*vorgegeben*). This point is also discussed in the *Ideas*, where Husserl notes that

> In my waking consciousness I find myself in this manner at all times, and without ever being able to alter the fact, in relation to the world which remains one and the same, though changing with respect to the composition of its contents. It is continually 'on hand' for me and I myself am a member of it.

and a few pages later the passage that was quoted earlier, in the section on intersubjectivity:

> I continually find at hand as something confronting me a spatiotemporal reality [*Wirklichkeit*] to which I belong like all other

human beings who are to be found in it and who are related to it as I am.

Also the passage from §37 of the *Crisis* that was quoted in the section on existence above expresses this same idea:

> The lifeworld . . . is always there, existing in advance for us, the 'ground' of all praxis, whether theoretical or extratheoretical. The world is pregiven to us . . .

Science and the lifeworld. A contested point in Husserl scholarship is the relation between the lifeworld and the sciences. Many interpreters of Husserl like to find an opposition to the sciences in the lifeworld. However, such a disdain for the sciences is out of character with Husserl's background in and continued interest in mathematics and science. It also accords poorly with the texts, which give us a different and more intriguing picture. According to Husserl, the lifeworld and the sciences are intimately connected, in three different ways:

(1) The sciences are *part* of the lifeworld. This comes out most explicitly and clearly in *Experience and Judgment*, where Husserl says:

> everything which contemporary natural science has furnished as determinations of what exists also belong to us, to the world, as this world is pregiven to the adults of our time. And even if we are not personally interested in natural science, and even if we know nothing of its results, still, what exists is pregiven to us in advance as determined in such a way that we at least grasp it as being in principle scientifically determinable.

Similar statements are also found elsewhere in Husserl's work, for example in the *Crisis*: 'Now the scientific world – [the subject matter of] systematic theory – . . . like all the worlds of ends "belongs" to the lifeworld'.

(2) Scientific statements get their *meaning* by being embedded in the lifeworld. This was stressed by Husserl already in the manuscript from 1915, quoted in §12 above:

> All opinions, justified or unjustified, popular, superstitious, scientific, all relate to the already *pregiven world* . . . . All theory relates to this immediate givenness and can have a legitimate *sense* only when it forms thoughts which do not offend against the general sense of the immediately given. No theorizing may offend against this sense.
>
> (emphasis added)

(3) The sciences are *justified* through the lifeworld. There is an interplay between this point and point (1) above; the sciences are justified because they belong to the lifeworld, and at the same time they belong to the lifeworld because they are conceived of as describing the world, as claiming to be true:

> Though the peculiar accomplishment of our modern objective science may still not be understood, nothing changes the fact that it is a validity for the lifeworld, arising out of particular activities, and that it belongs itself to the concreteness of the lifeworld.
>
> (*Crisis*)

And similarly:

> all these theoretical results have the character of validities for the lifeworld, adding themselves as such to its own composition and belonging to it even before that as a horizon of possible accomplishments for developing science. The concrete lifeworld, then, is the grounding soil [*der gründende Boden*] of the 'scientifically true' world and at the same time encompasses it in its own universal concreteness.
>
> (*Crisis*)

13 Ultimate justification

This brings us to the final theme of this presentation of Husserl's phenomenology: the role of the lifeworld in justification. The traditional interpretation of Husserl attributes to him a 'foundationalist' position: he is alleged to hold that we can reach absolute certainty with regard to a number of matters, particularly in philosophy. However, there is considerable evidence that Husserl had a view on justification similar to that of Goodman and Rawls. An opinion is justified by being brought into 'reflective equilibrium' with the *doxa* of our lifeworld. This holds even for mathematics: 'mathematical evidence has its source of meaning and of legitimacy in the evidence of the lifeworld' (*Crisis*).

A major puzzle that many see in this idea of justification is, 'How can appeal to the subjective-relative doxa provide any kind of justification for anything? It may help to resolve disagreements, but how can it serve as justification?' Husserl answers by pointing out that there is no other way of justifying anything, and that his way is satisfactory:

> What is actually first is the 'merely subjective-relative' intuition of prescientific world-life. For us, to be sure, this 'merely' has, as an old inheritance, the disdainful colouring of the *doxa*. In prescientific life itself, of course, it has nothing of this; there it is a realm of good

> verification and, based upon this, of well-verified predicative cognitions and of truths which are just as secure as is necessary for the practical projects of life that determine their sense. The disdain with which everything 'merely subjective and relative' is treated by those scientists who pursue the modern ideal of objectivity changes nothing of its own manner of being, just as it does not change the fact that the scientist himself must be satisfied with this realm whenever he has recourse, as he unavoidably must have recourse, to it.
>
> (*Crisis*)

So far, this is a mere claim. However, Husserl elaborates his view in other parts of his work. His key observation, which is an intriguing contribution to our contemporary discussion of ultimate justification, is that the 'beliefs', 'expectations' or 'acceptances' on which we ultimately fall back are unconsidered, and in most cases have never been considered. Every claim to validity and truth rests upon this 'iceberg' of unconsidered prejudgmental acceptances discussed earlier. One would think that this would make things even worse. Not only do we fall back on something that is uncertain, but on something that we have not even thought about, and have therefore never subjected to conscious testing. Husserl argues, however, that it is just the unconsidered nature of the lifeworld that makes it the ultimate ground of justification. 'Acceptance' and 'belief' are not attitudes that we decide to have through any act of judicative decision. What we accept, and the phenomenon of acceptance itself, are integral to our lifeworld, and there is no way of starting from scratch, or 'to evade the issue here through a preoccupation with aporia and argumentation nourished by Kantor Hegel, Aristotle or Thomas' (*Crisis*). Only the lifeworld can be an ultimate court of appeal: 'Thus alone can that ultimate understanding of the world be attained, behind which, since it is ultimate, there is nothing more that can be sensefully inquired for, nothing more to understand' (*Formal and Transcendental Logic* 1929) (see PHENOMENOLOGY, EPISTEMIC ISSUES IN).

14 Influence

Husserl's phenomenology has been a major influence on philosophy in our century, primarily on the continent, but since the 1970s also in the United States, Britain and several other countries. Husserl's immediate successor in Freiburg, Martin HEIDEGGER, conceived of *Being and Time* (1927) as a phenomenological study and dedicated it to Husserl. Also Jean-Paul SARTRE received strong impulses from Husserl, particularly from Husserl's idea that our material surroundings do not uniquely determine our noema. Sartre developed this idea into a philosophy of freedom, notably in *Being and Nothingness* (1943), which has the subtitle 'A Phenomenological Essay on Ontology'. Also Emmanuel LEVINAS, Paul RICOEUR and several other French philosophers were heavily influenced by Husserl. A new generation of young French and German philosophers is now combining Husserl scholarship with work on systematic issues in epistemology, philosophy of language and philosophy of mind.

Husserl's conception of the lifeworld become important for the so-called 'new hermeneutics' (Heidegger and GADAMER; see HERMENEUTICS) and for the methodology of the humanities and the social sciences (Schütz, Luckmann), largely because it provides a framework for discussing the subjective perspective and the many features of our way of structuring the world of which we are unaware and that often reflect the culture in which we have grown up. The issues connected with intersubjectivity and Husserl's exploration of the various ways in which we adapt to one another and come to conceive the world as a common world were pursued by several of his students, notably Edith Stein, in her dissertation *On the Problem of Empathy* (1917). His ideas about the role of the body, of kinesthesis and of practical activity, recur in different versions in Heidegger's existentialism and in Merleau-Ponty's phenomenology. MERLEAU-PONTY in particular is generous in the credit he gives Husserl.

Husserl's many students and followers explored a number of other themes in Husserl and applied his ideas in a variety of fields. Thus Roman INGARDEN used them in aesthetics, Aron Gurwitsch and several others in the study of perception. Husserl's views have led to new developments in psychology and psychotherapy. They have influenced philosophers of mathematics, including Gödel, and they are beginning to have an impact on the philosophy of mind and on cognitive science.

DAGFINN FØLLESDAL

HUTCHESON, FRANCIS (1694–1746)

Francis Hutcheson is best known for his contributions to moral theory, but he also contributed to the development of aesthetics. Although his philosophy owes much to John Locke's empiricist approach to ideas and knowledge, Hutcheson was sharply critical of Locke's account of two important normative ideas, those of beauty and virtue. He rejected Locke's claim that these ideas are mere constructs of the mind that neither copy nor make reference to anything objective. He also complained that Locke's account of human pleasure and pain was too narrowly focused. There are pleasures and pains other than those that arise in conjunction with ordinary sensations; there are, in fact, more than five senses. Two additional senses, the sense of beauty and the moral sense, give rise to distinctive pleasures and pains that enable us to make aesthetic and moral distinctions and evaluations.

Hutcheson's theory of the moral sense emphasizes two fundamental features of human nature. First, in contrast to Thomas Hobbes and other egoists, Hutcheson argues that human nature includes a disposition to benevolence. This characteristic enables us to be, sometimes, genuinely virtuous. It enables us to act from benevolent motives, whereas Hutcheson identifies virtue with just such motivations. Second, we are said to have a perceptual faculty, a moral sense, that enables us to perceive moral differences. When confronted with cases of benevolently motivated behaviour (virtue), we naturally respond with a feeling of approbation, a special kind of pleasure. Confronted with maliciously motivated behaviour (vice), we naturally respond with a feeling of disapprobation, a special kind of pain. In short, certain distinctive feelings of normal observers serve to distinguish between virtue and vice. Hutcheson was careful, however, not to identify virtue and vice with these feelings. The feelings are perceptions (elements in the mind of observers) that function as signs of virtue and vice (qualities of agents). Virtue is benevolence, and vice malice (or, sometimes, indifference); our moral feelings serve as signs of these characteristics.

Hutcheson's rationalist critics charged him with making morality relative to the features human nature happens at present to have. Suppose, they said, that our nature were different. Suppose we felt approbation where we now feel disapprobation. In that event, what we now call 'vice' would be called 'virtue', and what we call 'virtue' would be called 'vice'. The moral sense theory must be wrong because virtue and vice are immutable. In response, Hutcheson insisted that, as our Creator is unchanging and intrinsically good, the dispositions and faculties we have can be taken to be permanent and even necessary. Consequently, although it in one sense depends upon human nature, morality is immutable because it is permanently determined by the nature of the Deity.

Hutcheson's views were widely discussed throughout the middle decades of the eighteenth century. He knew and advised David Hume, and, while Professor of Moral Philosophy at Glasgow, taught Adam Smith. Immanuel Kant and Jeremy Bentham, among other philosophers, also responded to his work, while in colonial America his political theory was widely seen as providing grounds for rebellion against Britain.

DAVID FATE NORTON

HYPATIA (*c.* AD 370–415)

The Greek philosopher Hypatia was a Neoplatonist. She was famous for her public talks on philosophy and astronomy, and her forthright attitude to sex. Alhough concerned with higher knowledge, she was also a political animal and had a keen sense of practical virtue. She was killed by a Christian mob, and has remained since a martyr to the cause of philosophy.

IBN RUSHD, ABU'L WALID MUHAMMAD (1126–98)

Ibn Rushd (Averroes) is regarded by many as the most important of the Islamic philosophers. A product of twelfth-century Islamic Spain, he set out to integrate Aristotelian philosophy with Islamic thought. A common theme throughout his writings is that there is no incompatibility between religion and philosophy when both are properly understood. His contributions to philosophy took many forms, ranging from his detailed commentaries on Aristotle, his defence of philosophy against the attacks of those who condemned it as contrary to Islam and his construction of a form of Aristotelianism which cleansed it, as far as was possible at the time, of Neoplatonic influences.

His thought is genuinely creative and highly controversial, producing powerful arguments that were to puzzle his philosophical successors in the Jewish and Christian worlds. He seems to argue that there are two forms of truth, a religious form and a philosophical form, and that it does not matter if they point in different directions. He also appears to be doubtful about the possibility of personal immortality or of God's being able to know that particular events have taken place. There is much in his work also which suggests that religion is inferior to philosophy as a means of attaining knowledge, and that the understanding of religion which ordinary believers can have is very different and impoverished when compared with that available to the philosopher.

When discussing political philosophy he advocates a leading role in the state for philosophers, and is generally disparaging of the qualities of theologians as political figures. Ibn Rushd's philosophy is seen to be based upon a complex and original philosophy of languages which expresses his critique of the accepted methods of argument in Islamic philosophy up to his time.

OLIVER LEAMAN

IBN SINA, ABU 'ALI AL-HUSAYN (980–1037)

Ibn Sina (Avicenna) is one of the foremost philosophers in the Medieval Hellenistic Islamic tradition that also includes al-Farabi and Ibn Rushd. His philosophical theory is a comprehensive, detailed and rationalistic account of the nature of God and Being, in which he finds a systematic place for the corporeal world, spirit, insight, and the varieties of logical thought including dialectic, rhetoric and poetry.

Central to Ibn Sina's philosophy is his concept of reality and reasoning. Reason, in his scheme, can allow progress through various levels of understanding and can finally lead to God, the ultimate truth. He stresses the importance of gaining knowledge, and develops a theory of knowledge based on four faculties: sense perception, retention, imagination and estimation. Imagination has the principal role in intellection, as it can compare and construct images which give it access to universals. Again the ultimate object of knowledge is God, the pure intellect.

In metaphysics, Ibn Sina makes a distinction between essence and existence; essence considers only the nature of things, and should be considered apart from their mental and physical realization. This distinction applies to all things except God, whom Ibn Sina identifies as the first cause and therefore both essence and existence. He also argued that the soul is incorporeal and cannot be destroyed. The soul, in his view, is an agent with choice in this world between good and evil, which in turn leads to reward or punishment.

Reference has sometimes been made to Ibn Sina's supposed mysticism, but this would appear to be based on a misreading by Western philosophers

of parts of his work. As one of the most important practitioners of philosophy, Ibn Sina exercised a strong influence over both other Islamic philosophers and medieval Europe. His work was one of the main targets of al-Ghazali's attack on Hellenistic influences in Islam. In Latin translations, his works influenced many Christian philosophers, most notably Thomas Aquinas.

SALIM KEMAL

IDEALISM

Introduction

Idealism is now usually understood in philosophy as the view that mind is the most basic reality and that the physical world exists only as an appearance to or expression of mind, or as somehow mental in its inner essence. However, a philosophy which makes the physical world dependent upon mind is usually also called idealist even if it postulates some further hidden, more basic reality behind the mental and physical scenes (for example, Kant's things-in-themselves). There is also a certain tendency to restrict the term 'idealism' to systems for which what is basic is mind of a somewhat lofty nature, so that 'spiritual values' are the ultimate shapers of reality. (An older and broader use counts as idealist any view for which the physical world is somehow unreal compared with some more ultimate, not necessarily mental, reality conceived as the source of value, for example Platonic Forms.)

The founding fathers of idealism in Western thought are Berkeley (theistic idealism), Kant (transcendental idealism) and Hegel (absolute idealism). Although the precise sense in which Hegel was an idealist is problematic, his influence on subsequent absolute or monistic idealism was enormous. In the USA and the UK idealism, especially of the absolute kind, was the dominating philosophy of the late nineteenth and early twentieth century, receiving its most forceful expression with F.H. Bradley. It declined, without dying, under the influence of G.E. Moore and Bertrand Russell, and later of the logical positivists. Not a few philosophers believe, however, that it has a future.

1 The general case for idealism

As the term will be used here, a philosopher is an idealist if and only if they believe that the physical world exists *either* (1) only as an object for mind, *or* (2) only as a content of mind, *or* (3) only as something itself somehow mental in its true character, a disjunction we shall sum up as the thesis that the physical is derivative from mind. Particular idealists may go further and say that everything whatsoever is derivative from mind except mind itself, but this would not be affirmed by, for example, KANT, who believed in things-in-themselves which may be neither mental nor mind-derivative; neither, perhaps, would it be accepted by SCHOPENHAUER, for whom Kant's things-in-themselves become an unconscious cosmic Will. Moreover, there is no one view of the status of so-called abstract objects or universals which seems required of an idealist (see ABSTRACT OBJECTS).

The mind-dependence of the physical has been argued for and developed in widely varying ways. For example, the idealist may be a monist or a pluralist about the mind(s) from which the physical is derivative. Very significant too is the contrast between idealisms which are more ontological and those which are more epistemological in their approach. The two great exemplars of each are George BERKELEY and Immanuel Kant, the founding fathers of Western idealism and sources of most subsequent arguments in its favour.

Ontological idealism affirms that a certain view of reality, in which the physical is mind-dependent, is absolutely true, and regards such elements of common sense or science as appear to conflict with this either as wrong or as only seemingly incompatible. Epistemological idealism is concerned, rather, to show that the most acceptable views of the physical world, which doubtless include the claim that it is not mind-dependent, are, indeed, only true-for-us, but that truth-for-us is the only kind of truth it makes sense to seek. (A more qualified epistemological idealism may allow that chinks of a more absolute truth may suggest themselves and be important, but hardly belong to the main body of what we should call knowledge.) Thus, for idealism of the second kind, the mind-dependence of the physical is not so much a claim as to what is true about it, as about the sort of truth which truth about it is.

2 Berkeleian ontological idealism

According to Berkeley, there are only two types of existent – spirits (or minds) and ideas. Physical objects, as we ordinarily conceive them, are collections of sensory ideas (sense impressions).

Thus an apple is simply a collection of such sensory appearances as we are immediately aware of when we say that we are perceiving it (including the sensation of eating it). As for things, or those aspects of things, which are not perceived by any finite mind, they are there: *either* in the secondary sense that they would come into our minds if we took appropriate steps (gave ourselves appropriate impressions of moving in certain ways) to have a look at them, a sniff of them or whatever; *or* they are being perceived by an infinite mind. The second alternative brings in God immediately, the first is only explicable by saying that they are ideas which God would produce in us as a result of our taking those steps. Either way, the idealist truth that physical objects are collections of ideas, taken together with the obvious fact that everything is as though they continued their existence when unobserved by finite minds, appears to Berkeley an incontestable proof of God's existence.

Two of the main reasons why Berkeley thought that the physical world must consist of ideas were:

(1) It is only if physical objects are conceived as collections of ideas which hang together in experience that we have any empirical evidence for their existence.

(2) It is generally admitted that the so-called secondary qualities of physical things only exist as ideas in our minds (see PRIMARY–SECONDARY DISTINCTION). Moreover, it could be proved by the way in which secondary qualities vary with the state of the observer, and the way in which they are inseparable from sensations of pleasure and pain. But the considerations which show that secondary qualities are mind-dependent show equally that the primary ones are too. (Presented shape varies with conditions of observation as much as colour.) Moreover, no one can conceive of primary qualities existing in the absence of secondary qualities, so that they can only exist tied up with the admittedly mind-dependent.

It is usual to say that Berkeley's line of thought works only if one already accepts doctrines which he adopted uncritically from Locke (as he understood him), namely that all we ever perceive are ideas, and that secondary qualities are mind-dependent. It is, therefore, worth emphasizing that arguments of an essentially Berkeleian sort can be presented, and have been influential, which do not depend upon this Lockean inheritance.

The core of these arguments will be: physical objects, as they present themselves to our senses, do so with qualities which we cannot suppose to exist except for a perceiving mind. Indeed, we cannot even conceive them lacking all such qualities. These qualities, with which things present themselves to the senses, include what we may call all their perspectival qualities (the thing is given with features which reflect the position from which it is seen or the way in which it is felt and so on), also hedonic and aesthetic qualities, and finally an organization of the perceptual field into foreground and background, and into certain *Gestalten*. However much you try to imagine a thing as it is in itself, apart from any observer, you will find yourself imagining it as having features which represent the rough position of an observer of it, how they feel about it, and how they organize their perceptual field. In short you can only imagine it with features which it could only have as a presence to some observer. Such reasoning continues to persuade those of a Berkeleian cast of mind that one cannot form any genuine conception of a physical world existing except as an object for an observer.

All this is likely to invite two objections. First, it may be said that you should distinguish between the representation (such as an image in your mind) and what that representation represents for you. Only certain features of the image serve a representative function. Now the fact that the image may have some of the features which an actual sense impression of it would have only if the thing were perceived in a certain way, does not mean that these features must be regarded as belonging to what is represented. To this it may be replied by the idealist that they do not deny that, by ignoring certain features of the image, you can regard only the others as playing a role in picturing the object; and that these need not include those which obviously imply presence to a subject. What they deny, in contrast, is that one can form any sort of representation which will, so-to-speak, positively depict the thing as existing without subject-implying features. And unless one can do this one has no real sense of what an unperceived thing could be like.

The second objection is that one can conceive what one cannot imagine. Surely you can *conceive* a physical thing without these subject-implying features even if you cannot *imagine* it. To this the idealist may reply that you do not really understand what you are thinking if you only think about it in words (and doubtless this is what the objector means by conceiving it). Really to bring before your mind the character of the situation you believe in requires that, using the expression broadly, you must *imagine* it, and this you cannot do except by imagining it as it would present itself to a certain observer.

Such a line of thought, though not precisely Berkeley's in detail, is Berkeleian in spirit and inspiration and it is likely to be a main plank of an ontological idealism which claims that unperceived physical reality is an impossibility. What positive

view of the world can be based upon such reflections? For Berkeley it showed that there must be a God who is responsible for those ideas which (after acting in a certain way) we have no choice but to experience and who keeps the whole system of ideas available to each individual spirit in conformity with a universal system of laws determining the appearances available to each.

However, there have been philosophers who put forward a phenomenalism supposed not to imply the existence of God. According to them, one can speak meaningfully of physical things as existing unperceived. However, these only exist in a secondary sense as compared with those which are actually perceived, and their existence in this secondary sense is only the fact that they are available for perception. That is, there are definite facts for each of us (according to what we would ordinarily call our position in space) which determine what perceptions are available or compulsory for us in response to what we do or suffer (what sensations of movement we give ourselves or are given). There is no need to suppose that there is some explanation for this; it must just be accepted as a brute fact.

This phenomenalism is often not classed as idealist because its reductive account of the physical is divorced not only from theism, but from any other conception of the world as shaped by Reason or other higher forms of Mind. It is a puzzle of intellectual history that some of those most influenced by Berkeley's views of physical reality have been among the most atheistic and, in the popular sense, most 'materialist' of thinkers (for example, T.H. Huxley, A.J. Ayer and, with qualifications, J.S. Mill).

3 Kantian transcendental idealism

A simple version of Kant might present him as a phenomenalist who supplemented his phenomenalism with the admission that there must be some explanation of why the sense experiences available to us are what they are, yet who regarded this explanation as unavailable to us except as the thesis that they result from unconscious operations which we (as we really are rather than as we appear to ourselves) conduct upon things-in-themselves of whose real character we can know nothing (except that it cannot be that of anything properly called physical). However, Kant's reasoning for his transcendental idealism is largely different from those deriving from, or inspired by, Berkeley (see Kant, I. §5).

For Kant there are two striking facts about our knowledge of the world which only his transcendental idealism can explain ('transcendental' means 'having to do with our cognitive powers'). First, we have a great deal of 'synthetic a priori' knowledge about it (see A priori; Analyticity). Thus we know that arithmetic and the axioms of Euclid apply to the physical world as a whole, that every physical or mental process occurs in conformity with universal causal laws, and that change requires a permanent substratum of matter which remains quantitatively the same. Second, neither a priori nor empirical knowledge can answer the great questions of human destiny, such as whether God exists and whether we are immortal. The only possible explanation of our synthetic a priori knowledge about the physical and, indeed, mental worlds is that it is really our knowledge of our own cognitive nature. Space and time are the forms of our perceptual intuition and the categories of causation, substance and accident and so on are the categories by which we construct the unitary world of our actual and possible experience out of unconscious stimuli which reach the hidden self from things-in-themselves (or 'noumena'), of whose character we must remain ignorant. And it is because we are ignorant of things-in-themselves that we cannot *know* the answers to the questions about God and immortality, for these concern absolute truth rather than that truth-for-us which is all that is available for knowledge. On the other hand, just because we cannot *know* the answers to these questions, we may have *faith* that they would suit our moral natures and show that, in spite of the causal determinism holding in the phenomenal world, we are responsible at some 'noumenal' level for our own adherence or otherwise to the categorical imperatives of morality.

Some of the details of Kant's theory are outmoded by the fact that science seems no longer committed to some of his supposedly synthetic a priori truths such as the axioms of Euclid and the universality of causation. However, the idea that the world as we know it owes, to an incalculable extent, its general character to our particular modes of perception and thought still has great force. In Berkeley there was no suggestion that what we know is created by our knowledge of it. The ideas which constitute the physical world are simply the ones which God has chosen to give himself and us and to organize in a certain way. Our knowledge of those we perceive is a fully accurate knowledge by direct acquaintance and the existence and character of others, as actualities or possibilities, is known by induction. In Kant, knowledge itself to a great extent creates its objects by unconscious operations upon unconscious stimuli reaching us from things-in-themselves whose real nature it leaves in darkness.

The distinction is somewhat subtle, since both the Berkeleian and Kantian, in effect, regard facts

about the physical world as facts about the perceptions we may obtain through sensations of movement in certain directions. However, the Berkeleian inheritance has mainly been to insist on the way in which the physical world cannot be conceived without sensory qualities which can only occur as contents of experience, while the Kantian inheritance has mainly been to insist on the way in which our cognition of the physical world interprets it by concepts which it *brings to* experience rather than *abstracts from* it.

In fact, Kant's position is nearer to Berkeley's than he himself allowed. According to Kant his idealism is transcendental, whereas Berkeley's is empirical. What this comes to is that Berkeley's idealism professes to give the absolute truth about the physical world, as a corrective to a realism which regarded it as existing independently of mind, while Kant accepted such realism, but claimed that it was only true for us, and that, as for the absolute truth about things which underlie it, we know nothing beyond the mere fact that there must be such an absolute truth (in the moral and theistic significance of which we may have faith).

4 German absolute idealism

The great figures in German absolute idealism were J.G. Fichte, G.W.F. Hegel and F.W.J. von Schelling (see Absolute, the). (The character of their considerable political influence cannot be considered here.) In effect, each agreed with Kant that ordinary common sense and 'scientific' (in our usual sense, not theirs, in which it referred to their own philosophic conclusions) truth about the physical world is only truth for us. But they went beyond Kant in holding that philosophy can put this in the context of an absolute and rationally demonstrated truth about an essentially spiritual world. In fact, Kant's attempt to close the door on attempts to know the ultimate truth of things opened it to some of the most robust claims ever made to have probed the mysteries of the universe.

For Kant the physical world only exists for us, and our knowledge of it is only truth for us. However, we can recognize that there must be two hidden determinants of it, modes of cognition which take place in our own hidden depths, and the unconscious non-physical stimuli from mysterious things-in-themselves out of which they make the familiar physical world. Fichte thought the postulation of such things-in-themselves quite unnecessary. If the knowable physical world is something whose form we construct unconsciously why should not the matter be something we determine unconsciously too? Thereby we avoid the nebulous hypothesis of things-in-themselves, and are left simply with our own indubitable existence and hidden depths thereof, of which we dimly sense the presence. Of course there is an external world or non-ego, but it exists only as something which the ego posits and does so for reasons the general character of which can be deciphered. For the ego wants to live a life of moral worth and this it can only do if it has obstacles to overcome; thus the external world it posits consists precisely in those obstacles whose over-coming is most morally valuable at its current stage of development.

But how is it that each ego shares a non-ego, as it evidently does, with other egos? Fichte has two related answers. One is that moral development is something which can only occur in a community, so that the different egos need to posit a shared non-ego giving them a common environment in which to work out their moral destiny. Second, as his thought developed, Fichte became clearer that the ego which is working out its moral destiny in each of us is really a single world-spirit living out an apparent multiplicity of lives. Fichte developed this account by way of a dialectical method which became the hallmark of German idealism (inspired by Kant for whom, however, it was rather a source of illusion than a means to truth) in which apparently opposed truths are successively reconciled in higher syntheses until absolute truth is reached. Thus was born absolute idealism, in which the reality behind both nature and finite mind is a single absolute mind or self in process of self-discovery or development. However, Fichte's brand of absolute idealism is sometimes also called 'subjective idealism', because it regards the natural world as existing only for the subjective experience of finite individuals, expressions of a single world self though they may be.

Schelling was originally a follower of Fichte, but his continually shifting versions of idealism tended to become more 'objective' or at least more positively concerned with nature for its own sake. The Absolute or universal self does not simply dream the physical world as the scene of moral endeavour but rather expresses itself in a parallel dialectic, both 'really' in the nature from which the mind arises and 'ideally' in the mind for which nature exists. The two come together eventually in philosophical understanding and, more concretely, in art.

Absolute idealism, and the dialectical method and ontology, reached its historically most important form in the philosophy of Hegel. For Hegel, the world consists in a series of terms each surpassing its (only sometimes temporal) predecessors by incorporating what was satisfactory in them, in a manner which reconciles in a higher synthesis

that in which they contradicted each other. The series begins with pure concepts, leading on to actual natural and then humanly historical processes and terminates in a community in the free service of which each individual can find themselves fulfilled and in the consciousness, in the minds of philosophers, of its total nature. Thus, everything exists as path to, and as fodder for, a rich communal spiritual life, but how far this means that nothing really exists except as a component within or object for consciousness or spirit, is controversial. Therefore, it is unclear how far Hegel was an idealist in our sense (as opposed to the broader sense mentioned parenthetically above).

Hegel and Schelling had originally seen themselves as partners in developing a new philosophy, but Hegel soon surpassed his at first better known associate in fame and influence. However, Schelling had his turn again on Hegel's death, developing a new so-called positive philosophy in which he rejected the high a priori road to the nature of existence which both thinkers had taken previously. Absolute idealism must appeal partly to empirical features of the world rather than merely cite them sometimes as illustrations of what reason can independently prove must be so. This more traditionally Christian philosophy sought to give God and man a freedom effectively denied them by Hegelianism. Its somewhat bizarre ontology also seemed to many to show German idealism in its death throes.

In different ways Fichte, Schelling and Hegel each held that the world could only be understood through realizing that it is the concrete actualization of concepts whose proper home is in the mind. This binds them to Kant, but they sought to go beyond him in explaining why the relevant categories are just as they are and why there is a real unity of experience common to apparently different minds: namely that, in the end, the world is the construction of one universal Mind or Reason. Each saw himself as drawing on SPINOZA as well as Kant, but as substituting an ultimate self or subject for Spinoza's substance.

Standing quite apart from these absolute idealists is the lonely but immensely influential figure of Arthur SCHOPENHAUER. Arguably the closest metaphysically, if not in mood, to Kant, and accepting in the main his transcendental idealism, he claimed to have discovered the true nature of the realm of things-in-themselves, regarding them as aspects of a single universal Will, manifesting itself as object for a subject (which was its own self fallen into a state of wretched self-assertion), from which it can escape only by a culmination of that denial of the will to live, characteristic, as he saw it, of sainthood.

5 Anglo-American absolute idealism

As German philosophers moved away from idealism in the later part of the nineteenth century, idealism of an essentially absolute kind became the dominant mode of philosophy in the UK and the USA (where, however, there were more serious rivals to it). This was motivated partly by the search for a form of religious belief which would be less vulnerable to Lyell and Darwin than traditional Christianity had been, and by an ethical viewpoint which would be rather nobler in its conception of the possibilities of human life than Benthamite utilitarianism. Some of these philosophers (for example John and Edward Caird, and William Wallace), were doctrinal Hegelians, utilizing Hegelianism to save Christianity.

More importantly original philosophers of an idealist persuasion during this period were T.H. GREEN and F.H. BRADLEY in the UK (also the very like-minded, though more Hegelian, Bernard BOSANQUET), and Josiah ROYCE in the USA. We can only mention in passing the very distinctive idealism already advanced by J.F. Ferrier in Scotland, which draws both on Berkeley and on German idealism. These thinkers were to various extents influenced by Kant and Hegel and the other German idealists, but in the case of Bradley, at least, something of the Berkeleian tradition is, perhaps unconsciously, present.

Green was anxious above all to show that the development of human life from animal origins could not be explained purely by way of natural selection, or indeed in any naturalistic way. Rather, must it be recognized as the gradual unfolding of the life of a universal spirit aspiring to fulfilment in an eventually virtuous form of human life. For empiricism and naturalism cannot explain the connectedness of the world, and the ability of the human mind to synthesize events of different times into a unitary history. This is only possible if the world is the expression of a single universal spirit of which each of us is an actualization in which it becomes aware of itself. The general upshot is quite Hegelian, but there is little use of Hegelian dialectic.

Bradley's metaphysics derives from two main reflections: first, that nothing is genuinely conceivable except experience with its various modes and contents; second, that what we describe as distinct things in relation to each other can only be adequately conceived as abstractions from a higher unity. In the end all things must, therefore, be abstractions from one single Cosmic Experience. With his denial of time's reality and his claim that Reality is really a single cosmic *Nunc Stans* whose ingredients only seem to be passing away in time, Bradley strikes a note which is perhaps more Platonic than Hegelian. Royce's absolute idealism

has a good deal in common with Bradley, but whereas for Bradley God was only a rather superior 'appearance' along with the ordinary things of daily life, for Royce the Absolute was God, being personal in a way that Bradley's Absolute was not.

6 Panpsychism

One of the main charges against idealism is that of 'cosmic impiety' (Santayana). Its tendency is to make the vast realm of nature simply a representation in a mind observing or thinking of it. This can hardly do justice either to its obstinacy (surely not primarily of our own making, whatever Fichte may have thought) or to its wonderfulness. Such reflections have led some of those who are persuaded of the basic idealist claim that unexperienced reality is impossible, to hold the panpsychist position that nature is composed of units which feel their own existence and relation to other things, just as truly, if less articulately, as we do (see PANPSYCHISM). This was the view of Royce, and Bradley thought it might be true. It was a main plank, somewhat eccentrically developed, of the German idealist Gustav FECHNER (and is perhaps adumbrated in Schelling); also of LEIBNIZ, who in this respect can be called an idealist.

Panpsychism of this sort has been most fully developed in recent times in the work of A.N. WHITEHEAD and of Charles Hartshorne. It is sometimes regarded as a synthesis of realism and idealism; realist because it gives the ultimate units of nature (whatever they are) a reality in themselves (as what they are for themselves); idealist because it denies unexperienced reality. When the inner sentient life of (the rest of) nature is thought of as unified with the subjective life of humans and animals (as it must be for a Bradley or a Royce) in one absolute consciousness, we have a form of absolute or objective idealism which quite avoids the anthropocentric character it had in the work of thinkers such as Fichte.

7 Personal idealism

Many thinkers of an idealist persuasion in the English-speaking world bridled somewhat at the downplaying of individual persons by absolute idealism, especially Bradley and to a lesser extent Royce. This led to the development, as the nineteenth century closed, of some forms of personal idealism for which reality is a community of independently real spirits (with or without a God as a *primus inter pares*) and the physical world their common object or construction. There is no great figure here, with the possible exception of J.M.E. MCTAGGART who espoused a highly individual form of pluralistic idealism. Otherwise the main proponent of personal idealism was the US philosopher, G.H. Howison, although eight Oxford philosophers published a manifesto under this label in 1902 (see PERSONALISM).

Anglo-American idealism was, for a time, widely thought to have been refuted by the work of G.E. MOORE and Bertrand RUSSELL in the UK and such pragmatists as JAMES and DEWEY in the USA (though there were certainly idealist features to the thought of these two Americans), but a contrary judgement is now not uncommon. Edmund Husserl's phenomenology remains influential in some quarters, and some agree with his eventual view that it implies a form of transcendental idealism (see HUSSERL, E.). Some regard the antirealism associated with Michael DUMMETT as idealist in spirit (see REALISM AND ANTIREALISM), while some of the continuing school of Wittgensteinians regard the thought of WITTGENSTEIN as a form of social idealism. Much closer to traditional idealism, however, is the conceptual idealism of the important US philosopher Nicholas Rescher (which synthesizes idealism and pragmatism) and idealist positions (not, it must be admitted, so far very influential) advocated in the UK by John Foster and, if he may say so, by the author of this entry.

IDEALIZATIONS

Scientific analyses of particular phenomena are invariably simplified or idealized. The universe does not contain only two bodies as assumed in Newton's derivation of Kepler's laws, or only one body as assumed in Schwarzschild's relativistic update; real economic agents do not act exclusively to maximize expected utilities, the surfaces of ordinary plate condensers are not infinitely

extended planes, and the sine of an angle is not equal in measure to the angle itself. There are many reasons for the use of such misdescriptions. First and foremost is the need to achieve mathematical tractability. Science gets nowhere unless numbers, or numerical constraints, are produced that can form the basis of predictions and explanations. Idealizations may also be required because of the unavailability of certain data or because of the absence of necessary auxiliary theories.

The philosophical problem is to make normative sense of this common but complex scientific practice. For example, how can theories be tested given that they connect to the world only through the intermediary of idealized descriptions? In what sense can there be scientific explanations if what is to be explained must be misdescribed before theory can be brought to bear? The fact that idealizations can often be improved, with corresponding salutary effect on the accuracy of prediction or usefulness of explanation, suggests that idealizations should be understood as part of some sort of convergent process.

IDEALS

Ideals are models of excellence. They can be moral or nonmoral, and either 'substantive' or 'deliberative'. Substantive ideals present models of excellence against which things in a relevant class can be assessed, such as models of the just society or the good person. Deliberative ideals present models of excellent deliberation, leading to correct or warranted ethical conclusions. Ideals figure in ethics in two opposed ways. Most centrally, ideals serve to justify ethical judgments and to guide people in how to live. Sometimes, however, ideals may conflict with moral demands, thereby testing the limits of morality.

Reliance upon ideals in the development of ethical theories seems unavoidable but raises difficult questions. How can the choice of a particular ideal be justified? How might conflicts between ideals and other values, especially moral demands, be resolved?

IDENTITY

Anything whatsoever has the relation of identity to itself, and to nothing else. Things are identical if they are one thing, not two. We can refute the claim that they are identical if we can find a property of one that is not simultaneously a property of the other. The concept of identity is fundamental to logic. Without it, counting would be impossible, for we could not distinguish in principle between counting one thing twice and counting two different things. When we have acquired the concept, it can still be difficult to make this distinction in practice. Misjudgments of identity are possible because one thing can be presented in many guises.

Identity judgments often involve assumptions about the nature of things. The identity of the present mature tree with the past sapling implies persistence through change. The non-identity of the actual child of one couple with the hypothetical child of a different couple is implied by the claim that ancestry is an essential property. Knowledge of what directions are involves knowledge that parallel lines have identical directions. Many controversies over identity concern the nature of the things in question. Others concern challenges to the orthodox conception just sketched of identity itself.

1 Exposition of a popular view

Identity is the relation that, necessarily, each thing has to itself and to nothing else. Thus Constantinople has the identity relation to Istanbul because Constantinople *is* Istanbul, the very same city. This relation is often called 'numerical' identity, to distinguish it from 'qualitative' identity, the relation of exact similarity. Although 'identical' twins might be qualitatively identical, they are not numerically identical, for there are two of them, not one. The formula '$x = y$' says that x and y are (numerically) identical.

Identity is governed by two basic logical principles, reflexivity and Leibniz's Law (see LEIBNIZ, G.W. §11). To say that the identity relation is reflexive is to say that for each thing x, $x = x$. Leibniz's Law says that if $x = y$ then whatever is true of x is also true of y; it is used in arguments such as 'Jack the Ripper was in Whitechapel last night, the Prince of Wales was not in Whitechapel last night; therefore Jack the Ripper is not the Prince of Wales'. Leibniz was not the first to formulate this law, which was known in antiquity. It is sometimes called the 'indiscernibility of identicals', not to be

confused with Leibniz's principle of the 'identity of indiscernibles', a kind of converse, which says (implausibly) that qualitative identity implies numerical identity (see IDENTITY OF INDISCERNIBLES). Reflexivity and Leibniz's Law characterize identity uniquely: it is provably impossible for two non-equivalent relations to satisfy both principles. The two principles also entail that identity is symmetric (if $x = y$ then $y = x$) and transitive (if $x = y$ and $y = z$ then $x = z$).

If $a = b$, Leibniz's Law says that whatever is true of *a* is true of *b*. However, this permits the replacement of '*a*' by '*b*' only in contexts in which the expressions merely specify which thing is being talked about. For example, it is invalid to argue from 'Jocasta = the mother of Oedipus' and 'Oedipus knows that he married Jocasta' to 'Oedipus knows that he married the mother of Oedipus', for here 'the mother of Oedipus' does not merely specify a person; it specifies the description under which Oedipus is said to know that he married her (see PROPOSITIONAL ATTITUDES). Looking at photographs of a mature tree and a sapling, one cannot use Leibniz's Law to refute the hypothesis 'The mature tree = the sapling' on the grounds that 'The mature tree is tall' is true and 'The sapling is tall' is false. The noun phrases 'the mature tree' and 'the sapling' do not merely specify trees; they indicate the times with respect to which tallness is predicated. A correct understanding of Leibniz's Law is needed if identity through change is not to seem contradictory.

A genuine consequence of Leibniz's Law is the necessity of identity: things that are in fact identical could not have been distinct. For suppose that $x = y$. Since x could not have been distinct from itself, x could not have been distinct from y. Thus x and y cannot be contingently identical: they must be identical in all circumstances. A more complex argument concludes that they cannot be contingently distinct. They are either necessarily identical or necessarily distinct. Consequently, they are either always identical or always distinct. For example, if my headache is identical with an event in my brain, then that headache has to be that event; neither could exist without the other. Of course, a sentence such as 'Rome = the capital of Italy' is contingently true, but that is because the description 'the capital of Italy' need not have specified the city it actually specifies. The example is consistent with the necessity of identity, however, for it does not imply that one city could have been each of two.

An argument like that for the necessity of identity can be used to refute the idea that questions of identity need have no right answer. For example, it is sometimes held to be indeterminate whether a given mass of rock and ice is Everest (see VAGUENESS). However, it is determinate whether Everest is Everest. If Leibniz's Law and ordinary logic apply in this context, it follows that Everest is distinct from that mass, and the identity question has a right answer – a negative one. Thus the hypothesis of indeterminacy contradicts itself.

Statements of identity in natural languages often include a noun answering the question 'same what?', for example, 'Istanbul is the same city as Constantinople'. Since identity is uniquely characterized by its logic, the role of the noun is not to disambiguate 'same'; '*a* is the same *F* as *b*' is equivalent to '*a* is an *F* and $a = b$' (from which '*b* is an *F*' follows by Leibniz's Law). Identity is not defined kind by kind. Rather, we use the pregiven notion of identity in defining kinds. For example, we explain the difference between rivers and collections of water molecules by saying that the same river contains different collections of water molecules at different times.

A 'criterion of identity' for a kind is a necessary and sufficient condition for members of the kind to be identical. Frege's criterion of identity for directions is that the directions of lines are identical if and only if the lines are parallel. The criterion of identity for numbers is that the number of *F* things is the number of *G* things if and only if there is a one-to-one correlation between the *F* things and the *G* things. In such cases, members of the kind can be presented in various guises: directions as the directions of various lines; numbers as the numbers of various pluralities. The criterion of identity states the condition for two guises to be guises of one member of the kind. Without a grasp of these conditions, one would not know what directions or numbers were.

A criterion of identity for a spatiotemporal kind is expected to give the condition for a member of the kind at one place and time to be identical with a member of the kind at another place and time: for example, it may have to follow a continuous trajectory between these space-time points. An account may also be required of an object's identity across hypothetical circumstances. For example, one may hold that a member of the kind could not have originated at different places and times in different possible worlds. Spatiotemporal objects can be exactly similar without being identical, for they can originate at different times or places. In contrast, purely abstract objects cannot be exactly similar without being identical.

2 Alternatives

Every aspect of the preceding view has been questioned. Although it is popular, the philosophers who accept it all may be in a minority.

That identity is a relation has been denied, both on metaphysical grounds (it cannot relate two things) and on grammatical grounds (some assimilate 'is' in 'Constantinople is Istanbul' to the 'is' of predication as in 'Constantinople is crowded'). However, the logic of '=' does single out a unique class of ordered pairs of objects to which it applies, which suffices to make identity a relation in some minimal sense.

The contrast between identity and indiscernibility has been challenged, on the grounds that indiscernibles satisfy the same descriptions and since *a* satisfies the description 'identical with *a*', so does anything indiscernible from *a*. The obvious reply is that indiscernibles merely satisfy the same *intrinsic* descriptions, but it is hard to explain what 'intrinsicness' is.

Many applications of Leibniz's Law are problematic. Some deny its applicability to contexts that treat non-actual possibilities or even non-present times, thus excluding the derivation of the necessity or permanence of identity. The intention is, for example, to permit a pot to be contingently identical with the clay of which it is made, or the clay to be temporarily identical with the pot. One question is whether the envisaged restrictions on Leibniz's Law are *ad hoc*. They would not be if so-called identity between objects in different possible worlds or at different times could not be taken at face value but was somehow reducible to relations of qualitative similarity among counterpart objects each of which was confined to a single possible world or time. Such views have been supported by appeal to the difficulty of specifying what is essential to an object, for example, to what extent a particular ship could originally have been made from different planks of wood, or how much it could change without ceasing to exist. However, the proposed reductions are both complex and hard to reconcile with ordinary assumptions about the nature of everyday objects.

Identity has also been regarded as sometimes indeterminate. Although it is usually conceded that if things are identical then it is determinate whether they are identical, in some non-standard logics it does not follow that if it is indeterminate whether they are identical then they are not identical. Such logics postulate an intermediate status that propositions can have between truth and falsity. One challenge to this view is to explain what it means for a proposition to be not true without being false.

Yet another nonstandard view is the doctrine that identity is always relative to an answer to the question 'same what?'. For example, if *a* and *b* are copies of *Middlemarch*, this view disputes the inference from '*a* is the same edition as *b*' and '*a* is a copy' to '*a* is the same copy as *b*'. The relation of being the same edition will not satisfy Leibniz's Law unrestrictedly, but the view needs to show that no other relation (for example, being the same copy) could satisfy Leibniz's Law unrestrictedly, for such a relation would be a case of non-relative identity.

Many disputes about criteria of identity for particular kinds of entity (see PERSONAL IDENTITY) concern the nature of those entities, not of identity itself. But even the concept of a criterion of identity is itself problematic. For example, can one give an adequate criterion of identity for events by saying that events are identical if and only if they have the same causes and effects? The problem is that the causes and effects of events include other events. The criterion is in some sense circular, but it is hard to state the requirement of non-circularity clearly. Even if that could be done, it is unclear why every kind of object should have a non-circular criterion of identity. There may be nothing more basic than identity to which identity could be reduced. The standard logic of identity demands no such reduction.

Perhaps identity will come to be regarded as a logical constant, no more problematic than, say, conjunction. If so, many of the issues mentioned above will remain difficult, but their difficulty will concern the nature of various kinds of object, not the relation of identity.

TIMOTHY WILLIAMSON

IDENTITY OF INDISCERNIBLES

The principle of the identity of indiscernibles states that objects which are alike in all respects are identical. It is sometimes called Leibniz's Law. This name is also frequently used for the converse principle, the indiscernibility of identicals, that objects which are identical are alike in all respects. Both principles together are sometimes taken to define the concept of identity. Unlike the indiscernibility of identicals, which is widely accepted as a logical truth, the identity of indiscernibles principle has frequently been doubted and rejected. The principle is susceptible of more precise formulation in a number of ways, some more dubitable than others.

IDEOLOGY

An ideology is a set of ideas, beliefs and attitudes, consciously or unconsciously held, which reflects or shapes understandings or misconceptions of the social and political world. It serves to recommend, justify or endorse collective action aimed at preserving or changing political practices and institutions. The concept of ideology is split almost irreconcilably between two major senses. The first is pejorative, denoting particular, historically distorted (political) thought which reinforces certain relationships of domination and in respect of which ideology functions as a critical unmasking concept. The second is a non-pejorative assertion about the different families of cultural symbols and ideas human beings employ in perceiving, comprehending and evaluating social and political realities in general, often within a systemic framework. Those families perform significant mapping and integrating functions.

A major division exists within this latter category. Some analysts claim that the study of ideology can be non-evaluative in establishing scientific facts about the way political beliefs reflect the social world and propel people to specific action within it. Others hold that ideology injects specific politically value-laden meanings into conceptualizations of the social world which are inevitably indeterminate, and is consequently a means of constructing rather than reflecting that world. This also applies to interpretations undertaken by the analysts of ideology themselves.

IMAGINATION

'Imagination' and 'imagine' enjoy a family of meanings, only some of which imply the use of mental imagery. If I ask you to imagine a red flower, I will likely be inviting you to form an image. But if, for example, I say that I imagine that I will go to the party after taking a nap, I am not obviously giving voice to mental imagery. A variety of questions has arisen concerning imagination in its various forms, of which the following four are central. How do internal acts of imagining come to be about particular external objects and states of affairs, actual and non-actual? How are perceptual acts similar to and different from the central cases of imagining? To what extent do routine perception and cognition use cognitive resources similar to those of creative imagination? Are there any cognitive pursuits in which imagination can play a justificatory role?

IMMORTALITY OF THE SOUL

See Soul, nature and immortality of

IMPARTIALITY

On the one hand, most of us feel that we are permitted, even required, to give special consideration to the interests of ourselves and our loved ones; on the other hand, we also recognize the appeal of a more detached perspective which demands equal consideration for the interests of all. Among writers in the utilitarian tradition, some insist that the strictly impartial perspective is the only one that is ethically tenable, while others argue that a measure of institutionalized partiality can be justified as a means to maximizing welfare. An alternative tradition, stemming from Kant, sees the demand for impartiality as deriving from the importance of fairness and equal respect for persons, but tends to leave open the degree of partiality permitted. Finally, the Aristotelian conception of ethics offers a justification of partiality based on the structure of those virtuous dispositions of character (such as those involved in friendship and self-esteem) which are required for developing our distinctively human potentialities.

JOHN COTTINGHAM

IMPLICATURE

A term used in philosophy, logic and linguistics (especially pragmatics) to denote the act of meaning or implying something by saying something else. A girl who says 'I have to study' in response to 'Can you go to the movies?' has *implicated* (the technical verb for making an implicature) that she cannot go. Implicatures may depend on the conversational

context, as in this example, or on conventions, as when a speaker says 'He was clever but poor', thereby implying – thanks to the conventional usage of the word 'but' – that poverty is unexpected given intelligence. Implicature gained importance through the work of H.P. Grice. Grice proposed that conversational implicatures depend on a general principle of rational cooperation stating that people normally try to further the accepted purpose of the conversation by conveying what is true, informative, relevant and perspicuous. The extent and nature of the dependence, and the precise maxims involved, are matters of controversy. Other issues include whether certain implications are implicatures rather than presuppositions or parts of the senses (literal meanings) of the words used.

WAYNE A. DAVIS

INCOMMENSURABILITY

When one scientific theory or tradition is replaced by another in a scientific revolution, the concepts involved often change in fundamental ways. For example, among other differences, in Newtonian mechanics an object's mass is independent of its velocity, while in relativity mechanics, mass increases as the velocity approaches that of light. Earlier philosophers of science maintained that Einsteinian mechanics *reduces* to Newtonian mechanics in the limit of high velocities. However, Thomas Kuhn and Paul Feyerabend introduced a rival view. Kuhn argued that different scientific traditions are defined by their adherence to different *paradigms*, fundamental perspectives which shape or determine not only substantive beliefs about the world, but also methods, problems, standards of solution or explanation, and even what counts as an observation or fact. *Scientific revolutions* (changes of paradigm) alter all these profoundly, leading to perspectives so different that the meanings of words looking and sounding the same become utterly distinct in the pre- and post-revolutionary traditions. Thus, according to both Kuhn and Feyerabend, the concepts of mass employed in the Newtonian and Einsteinian traditions are incommensurable with one another, too radically different to be compared at all. The thesis that terms in different scientific traditions and communities are radically distinct, and the modifications that have stemmed from that thesis, became known as the thesis of incommensurability.

INDIAN AND TIBETAN PHILOSOPHY

Introduction

The people of South Asia have been grappling with philosophical issues, and writing down their thoughts, for at least as long as the Europeans and the Chinese. When Hellenistic philosophers accompanied Alexander the Great on his military campaigns into the Indus valley, on the western edge of what is now the Republic of India, they expressed delight and amazement upon encountering Indians who thought as they thought and lived the sort of reflective life that they recommended living.

Nearly all philosophical contributions in India were made by people writing (or speaking) commentaries on already existing texts; to be a philosopher was to interpret a text and to be part of a more or less well-defined textual tradition. It is common, therefore, when speaking of Indian philosophers, to identify them as belonging to one school or another. To belong to a school of philosophy was a matter of having an interpretation of the principal texts that defined that school. At the broadest level of generalization, Indians of the classical period were either Hindus, Buddhists or Jainas (see BUDDHIST PHILOSOPHY, INDIAN; HINDU PHILOSOPHY; JAINA PHILOSOPHY). In addition to these three schools, all of which were in some sense religious, there was a more secular school in the classical period, whose tenets were materialistic and hedonistic (see MATERIALISM, INDIAN SCHOOL OF). The end of the classical period in Indian philosophy is customarily marked by the arrival of Muslims from Turkey and Persia at the close of the first millennium. The contributions of Indian Muslims added to the richness of Indian philosophy during the medieval period (see ISLAMIC PHILOSOPHY).

Writing was introduced into Tibet not long after the arrival of Buddhism from India in the seventh century. The earliest literature of Tibet was made up

mostly of Buddhist texts, translated from Indian languages and from Chinese. Eventually, ideas associated with Bon, the indigenous religion of Tibet, were also written down. Tibetan philosophers followed the habit of Indians in that they made their principal contributions by writing commentaries on earlier texts. Key Buddhist philosophers from Tibet are SA SKYA PAṆḌITA (1182–1251), TSONG KHA PA BLO BZANG GRAGS PA (1357–1419), RGYAL TSHAB DAR MA RIN CHEN (1364–1432), MKHAS GRUB DGE LEGS DPAL BZANG PO (1385–1438) and MI BSKYOD RDO RJE (1507–54).

1 Hindu philosophy

The philosophical schools associated with what we now call Hinduism all had in common respect for the authority of the Veda ('Knowledge'), scriptures accepted as a revealed body of wisdom, cosmological information and codes of societal obligations. The textual schools that systematized disciplines derived from the Veda were the Mīmāṃsā, the Nyāya, the Vaiśeṣika, the Sāṅkhya and the various Vedānta schools (see MĪMĀṂSĀ; NYĀYA-VAIŚEṢIKA; SĀṄKHYA; VEDĀNTA). Concerned as all these schools were with correct interpretation of the Veda, it is natural that questions of language were of paramount importance in Indian philosophy (see LANGUAGE, INDIAN THEORIES OF; MEANING, INDIAN THEORIES OF). These involved detailed investigation into how subjects are to be defined and how texts are to be interpreted.

Closely related to questions of language were questions of knowledge in general and its sources (see EPISTEMOLOGY, INDIAN SCHOOLS OF). The two most important sources of knowledge that Indian philosophers discussed were sensation and inference, the theory of inference being important to the development of logic in India (see SENSE PERCEPTION, INDIAN VIEWS OF). Another topic about which Indian thinkers had much to say was the problem of how absences are known. Because of the importance of scriptures and religious teachers, epistemologists in India discussed the issue of the authority of texts and the question of the reliability of information conveyed through human language (see TESTIMONY IN INDIAN PHILOSOPHY). The questions associated with epistemology are in Indian philosophy often closely connected with questions of human psychology.

Most schools of Indian philosophy offered not only an epistemology but also an ontology. Many posited a personal creator god or an impersonal godhead. Just how particular things come into being through creative agency or through impersonal natural laws was a matter of considerable debate (see CAUSATION, INDIAN THEORIES OF). Indian thinkers also debated the precise nature of matter, the ontological status of universals, and how potentials become actualities.

In addition to epistemology and metaphysics, a third area that Indian systematic philosophers nearly always commented upon were issues concerning the nature of the human being. This included thoughts on a variety of ethical questions and the rewards for living an ethical life (see DUTY AND VIRTUE, INDIAN CONCEPTIONS OF). While most thinkers dealt with individual ethics, some also gave attention to the question of collective behaviour and policy.

The Hindu tradition produced a number of important individual philosophers. Among the earliest extant philosophers from India are the political theorist Kauṭilya (fourth century BC) and the grammarian and philosopher of language Patañjali (second century BC). The legendary founder of the Nyāya school, Akṣapāda Gautama, is traditionally regarded as the author of a set of aphorisms that modern scholars believe were composed in the second or third century. These aphorisms present the basic ontological categories and epistemological principles that were followed not only by the Nyāya school but by many others as well. The philosopher of language Bhartṛhari (fifth century) developed the intriguing idea that the basic stuff of which all the universe is made is an intelligence in the form of a readiness to use language. Vātsyāyana (fifth century) and Uddyotakara (sixth century) were both commentators on Gautama. The Vedānta systematist Śaṅkara (eighth century) wrote that realizing the underlying unity of all things in the form of Brahman could set one free. The aesthetician Abhinavagupta (tenth–eleventh century) made the education of the emotions through the cultivation of aesthetic sensitivity the basis of liberation from the turmoil of life. Udayana (eleventh century) of the Nyāya school developed important arguments for the existence of God. Rāmānuja (eleventh–twelfth century) and Madhva (thirteenth century), both Vedāntins, offered systems that became serious rivals to Śaṅkara's monism. The work of the logician Gageśa (fourteenth century), who revised the classical system of logic and epistemology, became the foundation for an important new school of thought, Navya-Nyāya ('New Nyāya'). Mādhava (fourteenth century) and Vallabhācārya (fifteenth–sixteenth century) made important contributions to Vedāntin philosophy. Gadādhara (seventeenth century) continued making advances in logical theory by building on the work of Gageśa. Also important in the sixteenth century were several thinkers who

commented upon the religious thinker Caitanya. Finally, there were several thinkers and movements in the nineteenth and twentieth centuries, a period during which Indian intellectuals struggled to reconcile traditional Indian ways of thinking with European and especially British influences.

2 Buddhist and Jaina philosophy

As was the case for Hindu philosophy, Buddhist and Jaina Philosophy in India tended to proceed through commentaries on already existing texts. Jainism was founded by Mahāvīra and is best known for its method of seeing every issue from every possible point of view. The principal Buddhist traditions that incorporated significant philosophical discussions were those that tried to systematize doctrines contained in various corpora of texts believed to be the words of the Buddha. An important issue for Buddhist thinkers, as for most Indian philosophers, was analysing the causes of discontent and suggesting a method for eliminating unhappiness, the cessation of suffering being a condition known as *nirvāṇa*. A doctrine of special interest to the Mādhyamika school was that everything is conditioned and therefore lacking independence. Some Buddhists developed the view that the conditioned world is so transitory that it disappears and is recreated in every moment (see MOMENTARINESS, BUDDHIST DOCTRINE OF). In the area of epistemology and philosophy of language, some Buddhists repudiated the Hindu confidence in the authority of the Veda.

The Buddhist tradition gave India a number of important philosophers, beginning with the founder of the religion, the Buddha (fifth century BC). The first important Buddhist philosopher to write in Sanskrit and the man traditionally regarded as the founder of the Mādhyamika school was Nāgārjuna (second century). A key commentator in both the Ābhidharmika schools and in the Yogācāra school was Vasubandhu (fifth century). Two key Buddhist epistemologists and logicians were Dignāga (fifth century) and Dharmakīrti (seventh century). Buddhism disappeared from northern India in the twelfth century and from southern India a few centuries later. In the twentieth century, there has been an effort to revive it, especially among the community formerly known as 'untouchables'. A remarkable leader of this community was Bhimrao Ramji Ambedkar.

3 Pronunciation of Sanskrit words

Sanskrit is an Indo-European language, closely related to Greek and Latin. In India, it is written in a variety of phonetic scripts, and in the West it is customary to write it in roman script. Many letters used to write Sanskrit are pronounced almost as they are in English; k, g, j, t, d, n, p, b, m, y, r, l, s and h can be pronounced as in English without too much distortion. The sound of the first consonant in the English word 'church' is represented by a simple 'c' in Sanskrit. In addition to these consonants there is a class of retroflex consonants, so called because the tongue is bent back so that the bottom side of the tongue touches the roof of the mouth. These sounds are represented by letters with dots under them: ṭ, ḍ, ṇ and ṣ. As in English, some consonants are heavily aspirated, so that they are pronounced with a slight puff of air. These consonants are represented by single letters in Indian scripts but by two-letter combinations in roman script; thus 'kh' is pronounced as the 'k' in English 'kill', 'th' as 't' in 'tame' (never as 'th' in 'thin' or 'there'), 'dh' as in 'mudhouse', and 'ph' as 'p' in 'pat' (never as 'ph' in 'philosophy'). The letter 'ś' is approximately like 'sh' in 'shingle'. The letter 'ṅ' is like 'ng' in 'finger' or 'nk' in 'sink', while 'ñ' is approximately like 'ny' in 'canyon'.

Vowels are pronounced approximately as in Spanish or Italian. Vowels with a macron over them (ā, ī and ū) are pronounced for twice as much time as their unmarked equivalents. The vowel 'ṛ' is pronounced with the tip of the tongue elevated towards the roof of the mouth, very much like the 'er' in the American pronunciation of 'carter'. The diphthongs 'ai' and 'au' are pronounced as 'i' in 'kite' and 'ou' in 'scout' (or almost as 'ei' and 'au' are pronounced in German) respectively. Accent tends to be on the third syllable from the end; thus the name 'Śāṅkara' sounds like 'SHANG-ka-ra', not 'shang-KA-ra'. If the second syllable from the end is long, then it is accented; 'Dignāga' is pronounced 'dig-NAA-ga'.

RICHARD P. HAYES

INDICATIVE CONDITIONALS

Examples of indicative conditionals are 'If it rained, then the match was cancelled' and 'If Alex plays, Carlton will win'. The contrast is with subjunctive or counterfactual conditionals, such as 'If it had rained, then the match would have been cancelled', and categoricals, such as 'It will rain'.

Despite the ease with which we use and understand indicative conditionals, the correct account of them has proved to be very difficult. Some say that 'If it rained, the match was cancelled' is equivalent to 'Either it did not rain, or the match was cancelled'. Some say that the sentence asserts that the result of 'adding' the supposition that it rained to the actual situation is to give a situation in which the match was cancelled. Some say that to assert that if it rained then the match was cancelled is to make a commitment to inferring that the match was cancelled should one learn that it rained. This last view is often combined with the view that indicative conditionals are not, strictly speaking, true or false; rather, they are more or less assertible or acceptable.

FRANK JACKSON

INDIRECT DISCOURSE

Indirect discourse is a mode of speech-reporting whereby a speaker conveys the content of someone's utterance without quoting the actual words. Thus, if Pierre says, 'Paris est belle', an English speaker might truly say,

(1) Pierre said that Paris is beautiful.

In English, sentences of indirect discourse often have the form 'A said that s', where 'A' refers to a person and 's' is often called the 'content sentence' of the report.

Sentences of indirect discourse have been classed with attributions of belief (and other psychological states) in view of an apparent conflict with the 'principle of the intersubstitutability of coreferring terms', which states that the truth-value of a sentence does not alter if one term in a sentence is replaced with another referring to the same thing. If (1) is true and 'Paris' and 'the City of Light' refer to the same thing, (2) may still be false:

(2) Pierre said that the City of Light is beautiful.

INDUCTION, EPISTEMIC ISSUES IN

Consider the following:

(1) Emeralds have been regularly dug up and observed for centuries; while there are still emeralds yet to be observed, every one observed so far has been green.

It is easy to see why we regard (1) as evidence, if true, that:

(2) Every emerald observed up until 100 years ago was green.

(1) logically implies (2): there is no way (1) could be true without (2) being true as well. It is less easy to see why we should think that (1), if true, is any evidence at all that:

(3) All hitherto unobserved emeralds are green as well.

(1) does not logically imply (3): it is consistent with (1) that (3) be false – that the string of exclusively green emeralds is about to come to an end. None the less, we *do* regard (1) as evidence, if true, that (3). What, if anything, justifies our doing so?

To answer this question would be to take a first step towards solving what is known as the 'problem of induction'. But only a first step. There is, at least on the surface, a wide variety of arguments that share the salient features of the argument from (1) to (3): their premises do not logically imply their conclusions, yet we think that their premises, if true, constitute at least some evidence that their conclusions are true. A fully fledged solution to the problem of induction would have to tell us, for each of these arguments, what justifies our regarding its premises as evidence that its conclusion is true. Still, the question as to how this step might be taken has been the focus of intense philosophical scrutiny, and the approaches outlined in this entry have been among the most important.

MARK KAPLAN

INDUCTIVE INFERENCE

Introduction

According to a long tradition, an inductive inference is an inference from a premise of the form 'all observed *A* are *B*' to a conclusion of the form 'all *A* are *B*'. Such inferences are not deductively valid, that is, even if the premise is true it is possible that the conclusion is false, since unobserved *A*s may differ from observed ones. Nevertheless, it has been held that the premise can make it reasonable to

believe the conclusion, even though it does not guarantee that the conclusion is true.

It is now generally allowed that there are many other patterns of inference that can also provide reasonable grounds for believing their conclusions, even though their premises do not guarantee the truth of their conclusions. In current usage, it is common to call all such inferences inductive. It has been widely thought that all knowledge of matters of fact that we have not observed must be based on inductive inferences from what we have observed. In particular, all knowledge of the future is, on this view, based on induction.

1 Paradigms of induction

The inference from 'all observed *A* are *B*' to 'all *A* are *B*', which was once taken to be the pattern for all inductive inference, is called (universal) *inductive generalization* or *enumerative induction*. A standard example is the inference from all observed ravens being black to all ravens being black. The fallibility of such inference is illustrated by the fact that, although all the swans seen by Europeans of the eighteenth century were white, black swans existed in Australia.

Some writers, such as J.S. Mill, argued that inductive generalization is the only legitimate kind of induction. However, as Mill was well aware, others have thought that there are other ways of making inferences from the observed to the unobserved. One method that has played an important role in philosophy of science is the method of hypothesis. In this method, the premises are that (i) hypothesis *H* implies a proposition *E* describing observable phenomena, and (ii) *E* is observed to be true; the conclusion is that *H* is true. In modern discussions this method is often called the hypothetico-deductive method, because *E* is supposed to be deduced from the hypothesis *H*.

The method of hypothesis is not deductively valid, since false hypotheses can have true consequences. Its defenders have argued that its premises can nevertheless make it reasonable to believe its conclusion. Descartes offered an example to support this position: if we find that a message in code makes sense when for each letter we substitute the following letter (B for A, C for B, and so on), we will be practically certain that this gives the true meaning of the message, especially if the message contains many words.

The method of hypothesis licenses conclusions that can never be reached by inductive generalization. For example, from the fact that observable phenomena are as they would be if matter consists of atoms, one may infer by the method of hypothesis that matter does consist of atoms. This conclusion could be reached by inductive generalization only if one had observed instances of matter composed of atoms, something that had not been done at the time that most scientists accepted the atomic theory of matter.

Other commonly recognized types of inductive inference are: (1) *statistical inductive generalization*, in which the premise is that *x* per cent of observed *A*s have been *B* and the conclusion is that about *x* per cent of all *A*s are *B*; (2) *predictive inference*, in which the premises are that *x* per cent of observed *A*s have been *B* and that *a* is *A*, the conclusion being that *a* is *B*; (3) *direct inference*, in which the premises are that *x* per cent of all *A*s are *B* and that *a* is *A*, the conclusion being that *a* is *B*; and (4) *inference by analogy*, in which the premises are that certain individuals have properties $F_1, \ldots, F_n$ and *a* also has $F_1, \ldots F_{n-1}$, the conclusion being that *a* also has F_n.

2 Induction in practice

It is generally allowed that the cogency of an inductive inference is greater the more observations that have been made and the more varied these observations have been. Mill also stressed that the reliability of an inductive generalization is greatly increased by finding that other similar generalizations hold up; conversely, he maintained that our knowledge of the variability of bird-colouring undermined the inductive generalization to the conclusion that all ravens are black. But the relevance of such considerations means that inductive inferences are not adequately represented by the paradigm forms listed above, since relevant information ought to be included in the premises.

Even if we added to the paradigm forms the sort of information just mentioned, they would still not adequately represent the inductive inferences that are made in everyday life and in science. For example, consider the inductive generalization to the conclusion that all ravens are black. The premise was that all observed ravens have been black. But observed by whom? If we say observed by anyone, then we cannot be sure that the premise is correct, and this ought to affect our confidence in the conclusion, though the argument does not provide for that. If we say observed by me, then the premise leaves out the very relevant information of what I know from the testimony of others. Further, even when the premise is limited to my own observation, I cannot be sure it is true; I could very well have

observed a white raven and mistakenly inferred from the fact that it was white that it was not a raven. Thus my confidence in the conclusion ought to depend on how closely I have examined both what I take to be ravens and what I take to be non-black things, though this is not reflected in the premise.

Another example: suppose we have weighed an object three times and obtained measurements of 4.9, 5.0 and 5.1 grams. From these results we might infer that the true weight of the object is between 4.7 and 5.3 grams. If this is to fit one of the standard forms, it will have to be the method of hypothesis. But the hypothesis that the true weight is between 4.7 and 5.3 grams does not entail that the weighings will give the results they did. In modern presentations of the hypothetico-deductive method it is commonly said that the premises include not only the hypothesis itself but also initial conditions, such as that the object was weighed three times, and auxiliary hypotheses, such as that the balance is accurate; but even with these additional premises the evidence does not follow deductively.

Since tests of hypotheses in science typically involve measurement, the preceding example is sufficient to show that science does not have much use for a method that is truly 'hypothetico-deductive'. But if the evidence only follows from the hypothesis with some probability, then it makes a difference what that probability is, though the method of hypothesis as usually presented does not include this information in the premises. As we will see below, it also makes a difference how probable the conclusion is on competing hypotheses, another relevant consideration that is not incorporated in the premises of the method of hypothesis as standardly conceived. Finally, our background information almost always gives us at least some relevant information; for example, we usually have some approximate idea what an object should weigh, and measurements that diverge too far from this will be taken to show that the balance is faulty. If the object that was weighed at 4.9, 5.0 and 5.1 grams was a loaded truck, we will conclude that there is something seriously wrong with the measurement process. The method of hypothesis does not provide a way to incorporate such relevant information.

3 Cogency

The premises of an inductive argument may provide more or less support for the conclusion. We would like to be able to identify the factors that determine the strength of this support. Some platitudes to this effect were mentioned above, but they have several defects. In particular, despite their vagueness, they are not true in general. For example, increasing the number of *A*s that have been observed to be *B* does not always make it more probable that all *A* are *B*; thus a person who died at age 149 is a person who died before age 150, but evidence that there is such a person would *reduce* the probability that all people die before age 150. In any case, those platitudes are limited to the paradigm forms of inductive inference, which we have seen is inadequate to represent actual inductive inferences. For these reasons, many contemporary theorists have looked for a more rigorous yet flexible framework for discussing the degree to which inductive premises support their conclusions. Probability theory has often been seen as providing such a framework.

Let H be a hypothesis and E some evidence. Let $\mathrm{P}(H)$ be the probability that H is true given the other information that we have besides E. Then the probability that we should give to H after learning E is the probability of H conditional on E, which we write as $\mathrm{P}(H \mid E)$. A theorem of probability, called Bayes' theorem (see PROBABILITY, INTERPRETATIONS OF §5), says the following (where $\bar{H}$ means H is false):

$$\mathrm{P}(H \mid E) = \frac{\mathrm{P}(E \mid H)}{\mathrm{P}(E \mid H)\mathrm{P}(H) + \mathrm{P}(E \mid \bar{H})\mathrm{P}(\bar{H})}\mathrm{P}(H)$$

We say that E confirms H if $\mathrm{P}(H \mid E) > \mathrm{P}(H)$. Assuming $\mathrm{P}(H) > 0$, E confirms H just in case the fraction on the right hand side of the above equation is greater than 1. Assuming $\mathrm{P}(H) < 1$, this condition will hold just in case $\mathrm{P}(E \mid H) > \mathrm{P}(E \mid \bar{H})$. Thus for evidence to confirm a hypothesis, it is not necessary that the evidence be entailed by the hypothesis, or even that the evidence be very probable given the hypothesis. Evidence that is quite improbable supposing the hypothesis to be true will confirm that hypothesis if the evidence is even less likely on the supposition that the hypothesis is false.

Another implication of the above equation is that even if evidence E does strongly confirm hypothesis H, it does not follow that the hypothesis has a high probability of being true, for its probability given other information may be quite low; that is, $\mathrm{P}(H \mid E)/\mathrm{P}(H)$ may be large and yet $\mathrm{P}(H \mid E)$ small, because $\mathrm{P}(H)$ is small. For example, when H is the hypothesis that a loaded truck weighs about 5 grams, $\mathrm{P}(H)$ is infinitesimal.

Philosophers often refer to the method of hypothesis as 'inference to the best explanation'. This terminology has the merit of recording the fact that the inference depends not just on the relation between hypothesis and evidence but also on how other hypotheses relate to the evidence. However, it

is wrong to suggest that *explanation* plays a fundamental role here; what is important in the connection between evidence and hypothesis is the probability of the evidence given the hypothesis, and this probability is not a measure of the degree to which the hypothesis explains the evidence (see Explanation; Inference to the best explanation). Furthermore, the terminology misleadingly suggests that the cogency of an inference is determined by the relation between the various hypotheses and the evidence, when in fact it depends also on the prior probability of the hypotheses.

4 Inference

Inductive inference has traditionally been understood as inference in the usual sense: on the basis of premises that are categorically accepted one comes to categorically accept another statement, the conclusion. For writers such as Bacon, Whewell and Mill, this conception was unproblematic. They thought that inductive inference could provide practical certainty on substantive matters of science and everyday life, and that where such certainty was lacking we should withhold assent. However, various factors, in particular the failure of such well-supported scientific theories as Newtonian mechanics, have convinced contemporary writers that substantive inductive conclusions always have some uncertainty, the best-supported scientific theories not excepted. This presents a dilemma: either we accept only those conclusions that are certain, in which case it seems we can accept very little and there will be almost no inductive inference, or else we accept conclusions that might be wrong.

Some writers on probability and induction, notably Carnap and Jeffrey, have embraced the first horn of this dilemma. They hold that induction should be conceived, not as a process by which we pass from some accepted statements to others, but rather as a process by which we assign probabilities to various hypotheses in the light of our evidence. On this view, we ought virtually never to make inductive inferences, as these have been traditionally conceived.

This rejection of inductive inference presupposes that acceptance of a hypothesis involves treating it as if it were certainly true. Some writers have argued that we can preserve the legitimacy of inductive inference by abandoning the assumption that someone who accepts a hypothesis must treat it as certainly true. A popular suggestion is that accepting a hypothesis is merely a matter of being highly confident of it, for example, of giving it a probability greater than some threshold. One objection to this view is that the set of propositions that have high probability is not consistent. For example, in a large unbiased lottery, the probability that any particular ticket will not win is high, though we also know that some ticket will win. Thus if we accepted every proposition with high probability we would accept an inconsistent set of propositions. This is called the 'lottery paradox' (see Paradoxes, epistemic). Another objection to equating acceptance with high probability is that informativeness is a reason for accepting a hypothesis but is not a reason for giving the hypothesis high probability.

Several writers have suggested that we ought to think of acceptance as a risky decision and use decision theory to evaluate when acceptance is rational (see Decision and game theory). The thought is that acceptance has a certain cognitive utility, which is greater if the proposition accepted is true than if it is false; acceptance of a hypothesis is rational, at least so far as cognitive goals are concerned, if it maximizes expected cognitive utility. The cognitive utility of accepting a true hypothesis is higher the more informative the hypothesis is, and thus this account provides a place for both probability and informativeness in determining the rationality of inductive inference. Some versions of this approach take acceptance to imply certainty while others do not.

PATRICK MAHER

INFERENCE TO THE BEST EXPLANATION

Inference to the best explanation is the procedure of choosing the hypothesis or theory that best explains the available data. The factors that make one explanation better than another may include depth, comprehensiveness, simplicity and unifying power. According to some, explanatory inference plays a central role in both everyday and scientific thinking. In ordinary life, a person might make the inference that a fuse has blown to explain why

several kitchen appliances stopped working all at once. Scientists also seem to engage in inference to the best explanation; for example, astronomers concluded that another planet must exist in order to account for aberrations in the orbit of Uranus. However, despite the suggestiveness of cases like these, the extent to which we do and should rely on inference to the best explanation is highly controversial.

INFINITARY LOGICS

An infinitary logic arises from ordinary first-order logic when one or more of its finitary properties is allowed to become infinite, for example, by admitting infinitely long formulas or infinitely long or infinitely branched proof figures. The need to extend first-order logic became pressing in the late 1950s when it was realized that many of the fundamental notions of mathematics cannot be expressed in first-order logic in a way that would allow for their logical analysis. Because infinitary logics often do not suffer the same limitation, they have become an essential tool in mathematical logic.

BERND BULDT

INFINITY

Introduction

The infinite is standardly conceived as that which is endless, unlimited, immeasurable. It also has theological connotations of absoluteness and perfection. From the dawn of civilization, it has held a special fascination: people have been captivated by the boundlessness of space and time, by the mystery of numbers going on forever, by the paradoxes of endless divisibility, and by the riddles of divine perfection.

The infinite is of profound importance to mathematics. Nevertheless, the relationship between the two has been a curiously ambivalent one. It is clear that mathematics in some sense presupposes the infinite, for instance in the fact that there is no largest integer. But the idea that the infinite should itself be an object of mathematical study has time and again been subjected to ridicule. The mathematical orthodoxy has been that there can be no formal theory of the infinite. In the nineteenth century this orthodoxy was challenged, with the advent of 'transfinite arithmetic'. Many, however, have remained sceptical, believing that the infinite is inherently beyond our grasp.

Perhaps their scepticism should be trained on the infinite itself: perhaps the concept is ultimately incoherent. It is certainly riddled with paradoxes. Yet we cannot simply jettison it. This is why the paradoxes are so acute. The roots of these paradoxes lie in our own finitude: it is self-conscious awareness of that finitude which gives us our initial sense of a contrasting infinite, and, at the same time, makes us despair of knowing anything about it, or having any kind of grasp of it. This creates a tension. We feel pressure to acknowledge the infinite, and we feel pressure not to. In trying to come to terms with the infinite, we are trying to come to terms with a basic conflict in ourselves.

1 Early Greek thought

The Greek word *peras* is usually translated as 'limit' or 'bound'. *To apeiron* denotes that which has no *peras*, the unlimited or unbounded: the infinite. *To apeiron* made its first significant appearance in early Greek thought with Anaximander of Miletus in the sixth century BC (see ANAXIMANDER). He thought of it as the boundless, imperishable, ultimate source of everything that is. He also thought of it as that to which all things must eventually return in order to atone for the injustices and disharmony which result from their transitory existence.

Anaximander was something of an exception, however. On the whole, the Greeks abhorred the infinite (as the old adage has it). More typical of that era were the Pythagoreans, a religious society founded by Pythagoras (see PYTHAGOREANISM). They believed in two basic cosmological principles, *Peras* and *Apeiron*, the former subsuming all that was good, the latter all that was bad. They held further that the whole of creation was to be understood in terms of, and indeed was ultimately constituted by, the positive integers 1, 2, 3, . . . ; and that this was made possible by the fact that *Peras* was continuously subjugating *Apeiron* (the integers themselves, of course, each being finite). The Pythagoreans were followed to some extent in these beliefs by Plato, who also held that it was the imposition of limits on the unlimited that accounted for all the numerically definable phenomena that surround us.

However, the Pythagoreans soon learned to their dismay that they could not simply relegate the

infinite to the role of cosmic villain. This was because of Pythagoras' own discovery that the square on the hypotenuse of a right-angled triangle is equal to the sum of the squares on the other two sides. Given this theorem, the ratio of a square's diagonal to each side is $\sqrt{2}:1$. There are some good approximations to this ratio: for example, it is a little more than 7:5 and a little less than 17:12. Indeed there are approximations of any desired degree of accuracy. Nevertheless, given the basic tenets of Pythagoreanism, it ought to be *exactly* p:q, for some pair of positive integers p and q. The problem was that they discovered a proof that it is not, which they regarded as nothing short of catastrophic. According to legend, one of them was shipwrecked at sea for revealing the discovery to their enemies. The Pythagoreans had stumbled across the 'irrational' within mathematics. They had seen the limitations of the positive integers, and had thereby been forced to acknowledge the infinite in their very midst.

At around the same time, ZENO OF ELEA was formulating various celebrated paradoxes connected with the infinite. Best known of these is the paradox of Achilles and the tortoise: Achilles, who runs much faster than the tortoise, cannot overtake it in a race if he lets it start a certain distance ahead of him. For in order to do so he must first reach the point from which the tortoise started, by which time the tortoise will have advanced a fraction of the distance initially separating them; he must then make up this new distance, by which time the tortoise will have advanced again; and so on *ad infinitum*. Such paradoxes, as well as having a profound impact on the history of thought about infinity, did much to reinforce early Greek hostility to the concept.

2 Aristotle

Aristotle's understanding of the infinite was an essentially modern one in so far as he defined it as the untraversable or never-ending. But he perceived a basic dilemma. On the one hand Zeno's paradoxes, along with a host of other considerations, show that the concept of the infinite really does resist a certain kind of application to reality. On the other hand there seems to be no prospect of doing without the concept, as the Pythagoreans had effectively realized. As well as $\sqrt{2}$, time seems to be infinite, numbers seem to go on *ad infinitum*, and space, time and matter all seem to be infinitely divisible.

Aristotle's solution to this dilemma was masterly. It has dominated all subsequent thought on the infinite, and until very recently was adopted by almost everyone who considered the topic. Aristotle distinguished between the 'actual infinite' and the 'potential infinite'. The actual infinite is that whose infinitude exists, or is given, at some point in time. The potential infinite is that whose infinitude exists, or is given, *over* time. All objections to the infinite, Aristotle insisted, are objections to the actual infinite. The potential infinite is a fundamental feature of reality. It is there to be acknowledged in any process which can never end: in the process of counting, for example; in various processes of division; or in the passage of time itself. The reason why paradoxes such as Zeno's arise is that we pay insufficient heed to this distinction. Having seen, for example, that there can be no end to the process of dividing a given racecourse, we somehow imagine that all those possible future divisions are already in effect there. We come to view the racecourse as already divided into infinitely many parts, and it is easy then for the paradoxes to take hold.

Even those later thinkers who did not share Aristotle's animosity towards the actual infinite tended to recognize the importance of his distinction. Often, though, Aristotle's reference to time was taken as a metaphor for something deeper and more abstract. This in turn usually proved to be something grammatical. Thus certain medieval thinkers distinguished between categorematic and syncategorematic uses of the word 'infinite'. Very roughly, to use the word categorematically is to say that there is something with a property that surpasses any finite measure; to use the word syncategorematically is to say that, given any finite measure, there is something with a property that surpasses it. In the former case the infinite has to be instantiated 'all at once'. In the latter case it does not.

The categorematic–syncategorematic distinction heralds another distinction, whose importance to the infinite is hard to exaggerate. This is the distinction between saying that there is something of kind X to which each thing of kind Y stands in relation R, and saying that each thing of kind Y stands in relation R to something of kind X (not necessarily the same thing each time). This is referred to below as the 'Scope Distinction' (see SCOPE).

But Aristotle himself was not thinking in these very abstract terms. He took the references to time in his own account of the actual–potential distinction quite literally, and this gave rise to his most serious difficulty. He held that time (unlike space) is infinite. He also held that time involves constant activity, as exemplified in the revolution of the heavens. When our attention is focused on the future, there is no obvious problem with this. Past revolutions, however, because they are past, seem to have an infinitude which is by now completely given to us, and hence which is actual. This difficulty, in various different guises, has been a continual aggravation for philosophers who have wanted to see the infinite in broadly Aristotelian terms.

3 The rationalists and the empiricists

For over 2,000 years Aristotle's conception of the infinite was regarded as orthodoxy. Often this conception was motivated by a kind of empiricism: the actual infinite was spurned on the grounds that we can never encounter it in experience. But does the potential infinite fare any better in this respect? Is experience of an infinitude that is given *over* time any less problematic than experience of an infinitude that is given all at once? The more extreme of the British empiricists were hostile to the infinite in all its guises. Where Aristotle had felt able to accept that space and time were infinitely divisible, BERKELEY and HUME denied even that. They thought that the concept of the infinite was one that we could, and should, do without (see EMPIRICISM).

This was partly a backlash against their rationalist predecessors. The rationalists had argued that we could form an idea of the infinite, even though we could neither experience it nor imagine it. They thought that this idea was an innate one, and that it constituted, or helped to constitute, a vital insight into reality. They did not see any difficulty in this view. As Descartes put it, the fact that we cannot grasp the infinite does not preclude our touching it with our thoughts, any more than the fact that we cannot grasp a mountain precludes our touching it (see RATIONALISM).

Descartes believed that our idea of the infinite had been implanted in our minds by God (see DESCARTES, R. §6). Indeed this was the basis of one of his proofs of God's existence. Only a truly infinite being, Descartes argued, *could* have implanted such an idea in our minds. Note here the assimilation of the infinite to the divine: this was a legacy of medieval thought which is nowadays quite commonplace. But when the assimilation was first made, at the end of antiquity – most famously, by the Neo-Platonist PLOTINUS – it marked something of a turning point in the history of thought about the infinite. Until then there had been a tendency to hear 'infinite' as a derogatory term. Henceforth, it was quite the opposite.

The empiricists, meanwhile, needed to defend their rejection of the infinite against the charge that this invalidated contemporary mathematics. They had more or less sophisticated ways of doing so, though in the case of geometry, where the problem was at its most acute, Hume took the rather cavalier step of simply denying certain crucial principles that mathematicians took for granted. (Berkeley's chief concern was with the use of infinitesimals in the recently invented calculus. In fact, his reservations were perfectly justified: a century was to pass before they were properly addressed.)

4 Kant

Kant played his characteristic role of conciliator in the debate on the infinite (see KANT §§2, 5, 8). He had an empiricist scepticism about the infinite, based on the fact that we cannot directly experience it. Nevertheless, he sided with the rationalists by insisting that there are certain formal or structural features of what we experience, which are accessible a priori and which *do* involve the infinite. Thus he thought that space and time were infinite (both in the sense of being infinitely extended and in the sense of being infinitely divisible): it is written into the form of whatever we experience that there can also be experience of how things are further out, further in, earlier or later. These, on Kant's view, were mathematical truths, a priori and unassailable.

But there is a question about how the topology of space and time *can* be a priori. Kant's celebrated reply was that space and time are not features of 'things in themselves'; they are part of an a priori framework which we contribute to our experience of things. What then of the *contents* of space and time, the physical universe as a whole? This was different. Kant did not think that what was physical was constructed a priori. Nor, on the other hand, did he think that it was ultimately real, that is to say real in a way that transcends any possible access we have to it. It had no features, on Kant's view, that exceed what we are capable of grasping through experience. So here the concept of the infinite did resist application. It still had what Kant regarded as a legitimate *regulative* use. That is, we could proceed *as if* the physical universe as a whole were infinite, thereby encouraging ourselves never to give up in our explorations. But we ultimately had no way of making sense of such infinitude. Kant was forced to take an extreme empiricist line by denying that the physical universe as a whole is infinitely big, that it has infinitely many parts and, going this time beyond Aristotle (thus bypassing the difficulty that had beset Aristotle himself), that it is infinitely old.

However, there was a dilemma. Kant was also forced to deny that the physical universe is *finite* in each of these three respects. Apart from anything else, to postulate infinite empty space or time beyond the confines of the physical universe is itself to postulate that which exceeds what we are capable of grasping through experience.

This dilemma looks acute. Kant himself presented it in the form of a pair of 'antinomies'. These antinomies consisted of the principal arguments against the physical universe's being infinite in each of the specified respects, and the principal arguments against its being finite. But he believed that the dilemma contained the seeds of its own solution. If what is physical is not ultimately real –

if there is no more to it than what we are capable of experiencing – then we are at liberty to deny that there is any such thing as the physical universe as a whole. There are only the finite physical things that are accessible to us through experience. The physical universe as a whole is neither infinite nor finite. It does not exist.

Kant's solution involved him in a direct application of the Scope Distinction (see §2 above). On the one hand he affirmed that any finite physical thing is contained within something physical (as the earth, for instance, is contained within the solar system). On the other hand he denied that there is something physical (that is, some one physical thing, the universe as a whole) within which any finite physical thing is contained. Both of these, the affirmation and the denial, were grounded in the fact that there is nothing we can identify in space and time such that we cannot identify more. This is fundamentally a fact about us: the fact that we are finite. Our identifications are always incomplete. What Kant added, in an idealist vein, was that what we cannot identify does not exist. Here, as in so many other places, we see how deeply involved with human finitude Kant's philosophy was, and how seriously he took it.

5 Post-Kantian metaphysics of the infinite

Metaphysical thought about the infinite since Kant has continued to be just as deeply involved with human finitude. Existentialists in particular have been greatly exercised by it, especially in its guise of mortality. But they have also for the most part recognized an element of the infinite within us. This too is Kantian. Kant believed that we are free rational agents, and that when our agency is properly exercised, it has an unconditioned autonomy that bears all the hallmarks of the truly infinite. For Kant, this was something which exalts us. But for many of the existentialists, still preoccupied with the fundamental fact of human finitude, it is something which is responsible for the deepest tensions within us, and thus for the absurdity of human existence (see EXISTENTIALISM §2).

Hegel agreed with Kant that the truly infinite is to be found in the free exercise of reason (see HEGEL, G.W.F. §8). But he took this further than Kant. He argued that reason is the infinite ground of everything. Everything that happens, on Hegel's view, can be understood as the activity of a kind of world-spirit, and this spirit *is* reason.

This led Hegel to a very non-Aristotelian conception of the infinite. For Hegel, the infinite was the complete, the whole, the unified. Aristotle's conception of the infinite as the never-ending was in Hegel's view quite wrong. He explained this conception as arising from our finite attempts to assimilate the truly infinite. And he described Aristotelian infinity as a 'spurious', or 'bad', infinity – a mere succession of finite elements, each bounded by the next, but never complete and never properly held together in unity. Such 'infinitude' seemed to Hegel at turns nightmarish, then bizarre, then simply tedious, but always a pale, inadequate reflection of the truly infinite.

6 Modern mathematics of the infinite

Despite Kant's influence on Hegel, and despite his own commitment to infinite reason (as well as to infinite space), Kant certainly helped to propagate the Aristotelian tradition of treating the actual infinite with hostility and suspicion. As this tradition prevailed, the actual infinite came increasingly to be understood in the more general, non-temporal sense indicated in §2 above. Eventually, exception was being taken to any categorematic use of the word 'infinite'. The most serious challenge to this tradition, at least in a mathematical context, was not mounted until the nineteenth century, by CANTOR, whose mathematical contribution to this topic is unsurpassed.

Objections to the actual infinite had tended to be of two kinds. The first kind we have already seen: objections based on the fact that we can never encounter the actual infinite in experience. Objections of the second kind were based on the paradoxes to which the actual infinite gives rise. These paradoxes fall into two groups. The first group consists of Zeno's paradoxes and their variants. By the time Cantor was writing, however, the calculus (which had then reached full maturity) had done a great deal to mitigate these. Of more concern by then were the paradoxes in the second group, which had been known since medieval times. These were paradoxes of equinumerosity. They derive from the following principle: if (and only if) it is possible to pair off all the members of one set with all those of another, then the two sets must have just as many members as each other. For example, in a non-polygamous society, there must be just as many husbands as wives. This principle looks incontestable. However, if it is applied to infinite sets, it seems to flout Euclid's notion that the whole is greater than the part. For instance, it is possible to pair off all the positive integers with those that are even: 1 with 2, 2 with 4, 3 with 6 and so on.

Cantor accepted this principle. And, consistently with that, he accepted that there are just as many even positive integers as there are positive integers altogether. Far from being worried by this, he defined precisely what is going on in such cases, and then incorporated his definitions into a coherent,

systematic and rigorous theory of the actual infinite, ready to be laid before any sceptical gaze.

It might be expected that, on this understanding, all infinite sets are the same size. (If they are, that is not unduly paradoxical.) But much of the revolutionary impact of Cantor's work came in his demonstration that they are not. There are different infinite sizes. This is a consequence of what is known as Cantor's theorem: no set, and in particular no infinite set, has as many members as it has subsets. In other words, no set is as big as the set of its subsets. If it were, then it would be possible to pair off all its members with all its subsets. But this is not possible. Suppose there *were* such a pairing and consider the set of members paired off with subsets not containing them. Whichever member was paired off with *this* subset would belong to it if and only if it did not belong to it (see CANTOR'S THEOREM).

In the course of developing these ideas, Cantor laid down some of the basic principles of the set theory which underlay them; he devised precise methods for measuring how big infinite sets are; and he formulated ways of calculating with these measures. In short, he established transfinite arithmetic. No longer, it seemed, did the actual infinite have to be an object of abhorrence. But was it really so?

Cantor operated with what is often called the 'iterative' conception of a set. On this conception, a set is something whose existence is parasitic on that of its members: the members exist 'first'. Thus there are, to begin with, all those things that are not sets (planets, people, positive integers and so forth). Then there are sets of these things. Then there are sets of *these* things. And so on, without end. Each thing, and in particular each set, belongs to countless further sets. But there never comes a set to which each set belongs (another illustration of the Scope Distinction). The collection of all sets is not itself a set. It is a collection which, on Cantor's conception, is too big to be regarded as a set: its members cannot be given 'all at once'. There is something very natural about this conception. But there is also something very Aristotelian about it. Notice the temporal metaphor that sustains the conception. Sets are depicted as coming into being 'after' their members, in such a way that there are always more to come. Their collective infinitude, as opposed to the infinitude of any one of them, is potential, not actual. Moreover, it is this collective infinitude that has best claim to the title. For the properties that I listed at the outset as characterizing the standard conception of the infinite – endlessness, unlimitedness, immeasurability – more properly apply to the entire collection of sets than to any individual set. This is partly because of the very success that Cantor enjoyed in subjecting sets themselves to careful mathematical scrutiny. Consider the set of positive integers. Exactly what Cantor showed concerning this set is that it is limited in size. (The set of sets of positive integers has more members.) Indeed, he showed that we can give a precise mathematical measure to how big it is. There is a sense, then, in which he established that the set of natural numbers is 'really' finite, and that what is 'really' infinite is something of an altogether different kind. (He was not himself averse to talking in these terms.) It may well be that, in the end, Cantor's work served to corroborate the Aristotelian orthodoxy that 'real' infinitude can never be actual.

Brouwer, meanwhile, believed that Cantor had not shown sufficient respect for the first kind of objection to the actual infinite: that we cannot encounter it in experience. All Cantor had done, in Brouwer's view, was to demonstrate certain tricks that can be played with (finite) symbols, without addressing the question of how these tricks answer to experience. The relevant experience here – the experience to which any meaningful mathematical statement must answer, according to Brouwer and other members of his intuitionistic school – is our experience of time. It is by recognizing the possibility of separating time into parts, and then indefinitely repeating that operation over time, that we arrive at our idea of the infinite. And such infinitude is again potential, not actual – in the most literal sense (see INTUITIONISM).

There was a very different critique of Cantor's ideas in the work of Wittgenstein, though it led to similar results (see WITTGENSTEIN §15). Wittgenstein believed that insufficient attention had been paid (at least by those interpreting Cantor's work, if not by Cantor himself) to what he called the 'grammar' of the infinite, that is to certain fundamental constraints on what could count as a meaningful use of the vocabulary associated with infinity. In effect, Wittgenstein argued that the word 'infinite' could not be used categorematically.

7 Human finitude

Problems about the infinite, we have seen, are grounded in our own finitude. On the one hand our finitude prevents us from being able to think of anything, including the whole of reality, as truly infinite. On the other hand it also prevents us from being able to think of anything finite – anything to that extent within our grasp – as the whole of reality. One way to reconcile these would be to deny that there is any such thing as the whole of reality and to argue that there are only bits of reality, each a part of some other. Here once again we see application of the Scope Distinction: every bit of

reality is a part of something, but there is nothing of which every bit of reality is a part. Aristotle, Kant and even to an extent Cantor played out variations on this theme.

But one of the most pressing questions of philosophy still remains: in what exactly does our finitude consist? Some of the most striking features of that finitude are conditioned by our temporality. In particular, of course, there is the fact of our death. How are we to view death? Among the many subsidiary questions that this raises, there are two in particular which are superficially equivalent but between which it is important to distinguish. Putting them in the crudest possible terms (their refinement would be a large part of addressing them): (1) Is death a 'bad thing'? and (2) Would immortality be preferable to mortality?

It can easily look as if these questions must receive the same answer. True, no sooner does one begin refining them than one sees all sorts of ways in which a full, qualified response to one can differ from a full, qualified response to the other. But it is in any case important to see how, even at this crude level, there is scope for answering 'yes' and 'no' respectively. Very roughly, death is a bad thing because it closes off possibilities, but immortality would not be preferable to mortality because mortality is what gives life its most basic structure and, therewith, the possibility of meaning.

To answer 'yes' to (1) and 'no' to (2) in this way is once again to invoke the Scope Distinction. It is to affirm that at each time there is reason to carry on living for longer, while denying that there is reason to carry on living forever. Meaning, for self-conscious beings such as us, can extend further than any given limits. But it cannot extend further than them all.

If it is true that, in some sense, at some level, and with all the myriad qualifications that are called for, the answer to (1) is 'yes' and the answer to (2) is 'no', then, coherent though that is, it points to a basic conflict in us: while it would not be good never to die, it is nevertheless never good to die. That conflict is one of the tragedies of human existence. It is also a version of the original conflict which underlies all our attempts to come to terms with the infinite. In thinking about the infinite, we are thinking, at a very deep level, about ourselves.

INFORMATION THEORY

Information theory was established in 1948 by Claude Shannon as a statistical analysis of factors pertaining to the transmission of messages through communication channels. Among basic concepts defined within the theory are information (the amount of uncertainty removed by the occurrence of an event), entropy (the average amount of information represented by events at the source of a channel), and equivocation (the 'noise' that impedes faithful transmission of a message through a channel). Information theory has proved essential to the development of space probes, high-speed computing machinery and modern communication systems.

The information studied by Shannon is sharply distinct from information in the sense of knowledge or of propositional content. It is also distinct from most uses of the term in the popular press ('information retrieval', 'information processing', 'information highway', and so on). While Shannon's work has strongly influenced academic psychology and philosophy, its reception in these disciplines has been largely impressionistic. A major problem for contemporary philosophy is to relate the statistical conceptions of information theory to information in the semantic sense of knowledge and content.

KENNETH M. SAYRE

INGARDEN, ROMAN WITOLD (1893–1970)

Ingarden was a leading exponent of phenomenology and one of the most outstanding Polish philosophers. Representing an objectivist approach within phenomenology he stressed that phenomenology employs a variety of methods, according to the variety of objects, and aspires to achieve an original cognitive apprehension of these objects. Its aim is to reach the essence of an object by analysing the contents of appropriate ideas and to convey the results of this analysis in clear language. Ingarden applied his methods in many areas of philosophy. He

developed a pluralist theory of being and an epistemology which makes it possible to practise this discipline in an undogmatic manner and to defend the value of human knowledge. In the theory of values he developed an inspiring approach to the analysis of traditionally problematic areas. He was best known for his work in aesthetics, in which he analysed the structure of various kinds of works of art, the nature of aesthetic experience, the cognition of works of art and the objective character of aesthetic values. In general, he gave phenomenology a lucid and precise shape.

In the interwar period Ingarden was the main opponent in Poland of the dominant Lwów–Warsaw School (Polish Analytic School), which had a minimalistic orientation. The main lines of his own investigations emerged largely as a result of his regular debates with Husserl, in particular those concerning Husserl's transcendental idealism. Ingarden's best-known work, *Das literarische Kunstwerk* (*The Literary Work of Art*) (1931) has its origins in this debate.

INNATENESS

A wide range of things can be, and have been, thought to be innate: behavioural patterns, learning capacities (especially linguistic), emotional responses, concepts, beliefs and knowledge, to give some prominent examples.

The exact meaning of these claims is harder to pin down. For a philosopher committed to a doctrine like that of Plato, according to which the human soul exists before it becomes associated with a human body, the idea of being innate or inborn can be taken more or less literally – innate properties are those which the soul brings with it. But for those without any such metaphysic of pre-existence the innateness of X must be understood as a tendency to acquire or manifest X in the course of development. Innateness is then liable to appear as a matter of degree: some such tendencies (the 'most innate') may be virtually independent of the specific input (experience, diet etc.) to the organism in question, others may be activated only by any 'normal' input, others again – those that are 'acquired' (or 'least innate') – only by some quite specific course of experience.

Historically, positive claims about innateness are associated with platonism, negative ones with empiricism. Such controversies are closely related to the 'nature v. nurture' debate.

INNATENESS IN ANCIENT PHILOSOPHY

The idea that knowledge exists latently in the mind, independently of sense experience, is put forward in three of Plato's dialogues: the *Meno*, the *Phaedo* and the *Phaedrus*. The claim is that the human soul exists before it enters a body, and that in its pre-existent state it knows certain things, which it forgets at birth. What we call 'learning' during our mortal lives is in fact nothing but the recollection of pre-existent knowledge. In a particularly famous passage in the dialogue the *Meno*, the character Socrates sets an uneducated slave boy a geometrical puzzle. After asking a series of questions, he elicits the correct answer from the boy, which he claims existed in him all along, merely needing to be aroused by the process of recollection. Aristotle dismisses recollection quite brusquely and tries to explain human learning by appeal to sense perception. In post-Aristotelian philosophy, it unclear how far any theory of innateness was accepted. Most probably, the Stoics thought that in some sense moral concepts and beliefs arise from human nature, though they did not endorse a theory of pre-existence or recollection.

INTENSIONAL ENTITIES

Intensional entities are such things as concepts, propositions and properties. What makes them 'intensional' is that they violate the principle of extensionality; the principle that equivalence implies identity. For example, the concept of being a (well-formed) creature with a kidney and the concept of being a (well-formed) creature with a heart are equivalent in so far as they apply to the same things, but they are different concepts. Likewise, although the proposition that creatures with kidneys have kidneys and the proposition that

creatures with hearts have kidneys are equivalent (both are true), they are not identical. Intensional entities are contrasted with extensional entities such as sets, which do satisfy the principle of extensionality. For example, the set of creatures with kidneys and the set of creatures with hearts are equivalent in so far as they have the same members and, accordingly, are identical. By this standard criterion, each of the following philosophically important types of entity is intensional: qualities, attributes, properties, relations, conditions, states, concepts, ideas, notions, propositions and thoughts.

All (or most) of these intensional entities have been classified at one time or another as kinds of universals. Accordingly, standard traditional views about the ontological status of universals carry over to intensional entities. Nominalists hold that they do not really exist. Conceptualists accept their existence but deem it to be mind-dependent. Realists hold that they are mind-independent. *Ante rem* realists hold that they exist independently of being true of anything; *in re* realists require that they be true of something.

GEORGE BEALER

INTENSIONAL LOGICS

Intensional logics are systems that distinguish an expression's intension (roughly, its sense or meaning) from its extension (reference, denotation). The purpose of bringing intensions into logic is to explain the logical behaviour of so-called intensional expressions. Intensional expressions create contexts which violate a cluster of standard principles of logic, the most notable of which is the law of substitution of identities – the law that from a = b and P(a) it follows that P(b). For example, 'obviously' is intensional because the following instance of the law of substitution is invalid (at least on one reading): Scott = the author of *Waverley*; obviously Scott = Scott; so, obviously Scott = the author of *Waverley*. By providing an analysis of meaning, intensional logics attempt to explain the logical behaviour of expressions such as 'obviously'. On the assumption that it is intensions and not extensions which matter in intensional contexts, the failure of substitution and related anomalies can be understood.

Alonzo Church pioneered intensional logic, basing it on his theory of types. However, the widespread application of intensional logic to linguistics and philosophy began with the work of Richard Montague, who crafted a number of systems designed to capture the expressive power of natural languages. One important feature of Montague's work was the application of possible worlds semantics to the analysis of intensional logic. The most difficult problems concerning intensional logic concern the treatment of propositional attitude verbs, such as 'believes', 'desires' and 'knows'. Such expressions pose difficulties for the possible worlds treatment, and have thus spawned alternative approaches.

JAMES W. GARSON

INTENSIONALITY

The truth or falsity of many sentences depends only on which things are being talked about. Within intensional contexts, however, truth values also depend on *how* those things are talked about, not just on which things they are. Philosophers and logicians have offered different analyses of intensional contexts and the behaviour of terms occurring within them.

The extension of a term is the thing or things it picks out: for instance, the extension of 'the Big Dipper' is the stellar constellation itself. The intension of a term can be thought of as the way in which it picks out its extension. 'The Big Dipper' and 'the Plough' have the same extension – a particular constellation – but pick it out in different ways. The two terms have different intensions. There is much debate about how we should actually understand the notion of an intension (see Intensional entities).

For many classes of sentence, the substitution of one term for another with the same extension leaves the truth value unchanged, irrespective of whether the two terms also have the same intension. This is called intersubstitution *salva veritate* (preserving truth). For instance, if it is true that the Big Dipper consists of seven stars, then it is also true that the Plough consists of seven stars. In a number of important cases, however, terms with the same extension but different intensions are not intersubstitutable *salva veritate*. Consider, for instance:

1 Tom believes that the Big Dipper consists of seven stars.
2 Tom believes that the Plough consists of seven stars.

It is quite possible that Tom mistakenly believes that 'the Plough' refers to a totally different constellation consisting of only six stars, in which case (1) could be true and (2) false. Co-extensive terms cannot be intersubstituted *salva veritate* within the scope of the verb 'believes'. Such contexts are called intensional.

Other verbs which, like 'believe', refer to propositional attitudes – verbs like 'hope', 'desire',

'fear' – also create intensional contexts. Propositional attitudes are *intentional* states (note the 't') which has led some to consider the possible connections between inten*S*ionality and inten*T*ionality (see INTENTIONALITY). The two must be distinguished carefully, however, not least because intensional contexts are also created by non-psychological terms, most importantly modal terms like 'necessarily' and 'possibly'. The intensionality of modal contexts leads to particular difficulties when they also involve quantification; these problems have led to controversies over the interpretation not only of modal terms but also of the quantifiers (see QUANTIFIERS, SUBSTITUTIONAL AND OBJECTUAL).

The failure of intersubstitutability *salva veritate* raises questions about the behaviour of terms in intensional contexts. Frege argues that, in intensional contexts, the term 'the Big Dipper' in (1) refers not to the Big Dipper as usual but to its own intension (or, in Frege's terminology, its sense (see INDIRECT DISCOURSE; PROPER NAMES; SENSE AND REFERENCE). Quine describes intensional contexts as *referentially opaque*, arguing that terms occurring within them do not refer at all. Davidson's *paratactic* analysis of propositional attitude statements and of indirect discourse, another intensional context, tries to preserve our intuition that terms in intensional contexts work in the same way as in any other contexts (see INDIRECT DISCOURSE).

Many philosophers think that logic should have nothing to do with intensions. But the intensionality of many natural language contexts is hard to deny, and the development of intensional logics suggests that a more tolerant attitude might well pay off (see INTENSIONAL LOGICS).

SIMON CHRISTMAS

INTENTION

Suppose that Kevin intends to brush up on his predicate logic, and acts on this intention, because he wants to conduct a good tutorial and he believes that some preparatory revision will help him to do so. In an example like this, we explain why Kevin intends to revise his logic, and why he (intentionally) does revise it, by appealing to the belief and desire which provide his reasons both for his intention and his corresponding intentional action. But how does Kevin's intention to act, coming between his reasons and his action, help to explain what he does? Central questions in the theory of intention include the following: Are intentions distinct mental attitudes or are they analysable in terms of other mental attitudes – such as beliefs and desires? How is intending to do something related to judging that it is best to do it? What distinctive roles, if any, do intentions play in getting us to act? Are foreseen but undesired consequences of an intentional action intended?

INTENTIONAL FALLACY

See ARTIST'S INTENTION

INTENTIONALITY

Intentionality is the mind's capacity to direct itself on things. Mental states like thoughts, beliefs, desires, hopes (and others) exhibit intentionality in the sense that they are always directed on, or at, something: if you hope, believe or desire, you must hope, believe or desire something. Hope, belief, desire and any other mental state which is directed at something, are known as intentional states. Intentionality in this sense has only a peripheral connection to the ordinary ideas of intention and intending. An intention to do something is an intentional state, since one cannot intend without intending something; but intentions are only one of many kinds of intentional mental states.

The terminology of intentionality derives from the scholastic philosophy of the Middle Ages, and was revived by Brentano in 1874. Brentano characterized intentionality in terms of the mind's direction upon an object, and emphasized that the object need not exist. He also claimed that it is the intentionality of mental phenomena that distinguishes them from physical phenomena. These ideas of Brentano's provide the background to twentieth-century discussions of intentionality, in both the phenomenological and analytic traditions. Among these discussions, we can distinguish two general projects. The first is to characterize the essential features of intentionality. For example, is intentionality a relation? If it is, what does it relate, if the object of an intentional state need not exist in order to be thought about? The second is to explain how intentionality can occur in the natural world. How

can merely biological creatures exhibit intentionality? The aim of this second project is to explain intentionality in non-intentional terms.

TIM CRANE

INTERNALISM AND EXTERNALISM IN EPISTEMOLOGY

The internalism–externalism distinction is usually applied to the epistemic justification of belief. The most common form of internalism (accessibility internalism) holds that only what the subject can easily become aware of (by reflection, for example) can have a bearing on justification. We may think of externalism as simply the denial of this constraint.

The strong intuitive appeal of internalism is due to the sense that we should be able to determine whether we are justified in believing something just by carefully considering the question, without the need for any further investigation. Then there is the idea that we can successfully reply to sceptical doubts about the possibility of knowledge or justified beliefs only if we can determine the epistemic status of our beliefs without presupposing anything about which sceptical doubts could be raised – the external world for example.

The main objections to internalism are as follows. (1) It assumes an unrealistic confidence in the efficacy of armchair reflection, which is often not up to surveying our entire repertoire of beliefs and other possible grounds of belief and determining the extent to which they support a given belief. (2) If we confine ourselves to what we can ascertain on reflection, there is no guarantee that the beliefs that are thus approved as justified are likely to be true. And the truth-promoting character of justification is the main source of its value.

Externalism lifts this accessibility constraint, but in its most general sense it embodies no particular positive view. The most common way of further specifying externalism is reliabilism, the view that a belief is justified if and only if it was produced and/or sustained by a reliable process, one that would produce mostly true beliefs in the long run. This is a form of externalism because whether a particular belief-forming process is reliable is not something we can ascertain just on reflection. The main objections to externalism draw on internalist intuitions. (1) If the world were governed by an evil demon who sees to it that our beliefs are generally false, even though we have the kind of bases for them we do in fact have, then our beliefs would still be justified, even though formed unreliably. (2) If a reliable clairvoyant (one who 'sees' things at a great distance) forms beliefs on this basis without having any reason for thinking that they are reliably formed, those beliefs would not be justified, even though they pass the reliability test.

WILLIAM P. ALSTON

INTERNATIONAL RELATIONS, PHILOSOPHY OF

The philosophy of international relations – or more precisely its *political* philosophy – embraces problems about morality in diplomacy and war, the justice of international practices and institutions bearing on economic welfare and the global environment, human rights, and the relationship between sectional loyalties such as patriotism and global moral commitments.

Not everyone believes that such a subject can exist, or rather, that it can have significant ethical content. According to political realism – a widely-held view among Anglo-American students of international relations – moral considerations have no place in decisions about foreign affairs and international behaviour. The most extreme varieties of realism deny that moral judgment can have meaning or force in international affairs; more moderate versions acknowledge the meaningfulness of such judgments but hold either that leaders have no responsibility to attend to the morality of their actions in foreign affairs (because their overriding responsibility is to advance the interests of their constituents), or that the direct pursuit of moral goals in international relations is likely to be self-defeating.

Leaving aside the more sceptical kinds of political realism, the most influential orientations to substantive international morality can be arrayed on a continuum. Distinctions are made on the basis of the degree of privilege, if any, extended to the citizens of a state to act on their own behalf at the potential expense of the liberty and wellbeing of persons elsewhere. 'The morality of states', at one extreme, holds that states have rights of autonomy analogous to those of individuals within domestic society, which secure them against external interference in their internal affairs and guarantee their ownership and control of the natural and human resources within their borders. At the other end of the continuum, one finds cosmopolitan views which deny that states enjoy any special privilege; these views hold that individuals rather than states are the ultimate subjects of morality, and that value judgments concerning international conduct should take equally seriously the wellbeing of each person potentially affected by a decision, whether compatriot

or foreigner. Cosmopolitan views may acknowledge that states (and similar entities) have morally significant features, but analysis of the significance of these features must connect them with considerations of individual wellbeing. Intermediate views are possible; for example, a conception of the privileged character of the state can be combined with a conception of the international realm as weakly normative (that is, governed by principles which demand that states adhere to minimum conditions of peaceful coexistence).

The theoretical difference between the morality of states and a fully cosmopolitan morality is reflected in practical differences about the justifiability of intervention in the internal affairs of other states, the basis and content of human rights, and the extent, if any, of our obligations as individuals and as citizens of states to help redress the welfare effects of international inequalities.

INTUITIONISM

Ultimately, mathematical intuitionism gets its name and its epistemological parentage from a conviction of Kant: that intuition reveals basic mathematical principles as true a priori. Intuitionism's mathematical lineage is that of radical constructivism: constructive in requiring proofs of existential claims to yield provable instances of those claims; radical in seeking a wholesale reconstruction of mathematics. Although partly inspired by Kronecker and Poincaré, twentieth-century intuitionism is dominated by the 'neo-intuitionism' of the Dutch mathematician L.E.J. Brouwer. Brouwer's reworking of analysis, paradigmatic for intuitionism, broke the bounds on traditional constructivism by embracing real numbers given by free choice sequences. Brouwer's theorem – that every real-valued function on a closed, bounded interval is uniformly continuous – brings intuitionism into seeming conflict with results of conventional mathematics.

Despite Brouwer's distaste for logic, formal systems for intuitionism were devised and developments in intuitionistic mathematics began to parallel those in metamathematics. A. Heyting was the first to formalize both intuitionistic logic and arithmetic and to interpret the logic over types of abstract proofs. Tarski, Beth and Kripke each constructed a distinctive class of models for intuitionistic logic. Gödel, in his *Dialectica* interpretation, showed how to view formal intuitionistic arithmetic as a calculus of higher-order functions. S.C. Kleene gave a 'realizability' interpretation to the same theory using codes of recursive functions. In the last decades of the twentieth century, applications of intuitionistic higher-order logic and type theory to category theory and computer science have made these systems objects of intense study. At the same time, philosophers and logicians, under the influence of M. Dummett, have sought to enlist intuitionism under the banner of general antirealist semantics for natural languages.

DAVID CHARLES MCCARTY

INTUITIONISM IN ETHICS

To intuit something is to apprehend it directly, without recourse to reasoning processes such as deduction or induction. Intuitionism in ethics proposes that we have a capacity for intuition and that some of the facts or properties that we intuit are irreducibly ethical. Traditionally, intuitionism also advances the important thesis that beliefs arising from intuition have direct justification, and therefore do not need to be justified by appeal to other beliefs or facts. So, while intuitionism in ethics is about the apprehension of ethical facts or properties, traditional intuitionism is principally a view about how beliefs, including ethical beliefs, are justified. Varieties of intuitionism differ over what is intuited (for example, rightness or goodness?); whether what is intuited is general and abstract or concrete and particular; the degree of justification offered by intuition; and the nature of the intuitive capacity. The rejection of intuitionism is usually a result of rejecting one of the views that lie behind it.

Note that 'intuition' can refer to the thing intuited as well as the process of intuiting. Also, somewhat confusingly, intuitionism is sometimes identified with pluralism, the view that there is a plurality of fundamental ethical properties or principles. This identification probably occurs because pluralists often accept the epistemological version of intuitionism.

ROBERT L. FRAZIER

INTUITIONISTIC LOGIC AND ANTIREALISM

The law of excluded middle (LEM) says that every sentence of the form $A \vee \neg A$ ('A or not A') is

logically true. This law is accepted in classical logic, but not in intuitionistic logic. The reason for this difference over logical validity is a deeper difference about truth and meaning. In classical logic, the meanings of the logical connectives are explained by means of the truth tables, and these explanations justify LEM. However, the truth table explanations involve acceptance of the principle of bivalence, that is, the principle that every sentence is either true or false. The intuitionist does not accept bivalence, at least not in mathematics. The reason is the view that mathematical sentences are made true and false by proofs which mathematicians construct. On this view, bivalence can be assumed only if we have a guarantee that for each mathematical sentence, either there is a proof of the truth of the sentence, or a proof of its falsity. But we have no such guarantee. Therefore bivalence is not intuitionistically acceptable, and then neither is LEM.

A realist about mathematics thinks that if a mathematical sentence is true, then it is rendered true by the obtaining of some particular state of affairs, whether or not we can know about it, and if that state of affairs does not obtain, then the sentence is false. The realist further thinks that mathematical reality is fully determinate, in that every mathematical state of affairs determinately either obtains or does not obtain. As a result, the principle of bivalence is taken to hold for mathematical sentences. The intuitionist is usually an *antirealist* about mathematics, rejecting the idea of a fully determinate, mind-independent mathematical reality.

The intuitionist's view about the truth-conditions of mathematical sentences is not obviously incompatible with realism about mathematical states of affairs. According to Michael Dummett, however, the view about truth-conditions implies antirealism. In Dummett's view, a conflict over realism is fundamentally a conflict about what makes sentences true, and therefore about semantics, for there is no further question about, for example, the existence of a mathematical reality than as a truth ground for mathematical sentences. In this vein Dummett has proposed to take acceptance of bivalence as actually defining a realist position.

If this is right, then both the choice between classical and intuitionistic logic and questions of realism are fundamentally questions of semantics, for whether or not bivalence holds depends on the proper semantics. The question of the proper semantics, in turn, belongs to the theory of meaning. Within the theory of meaning Dummett has laid down general principles, from which he argues that meaning cannot in general consist in bivalent truth-conditions. The principles concern the need for, and the possibility of, manifesting one's knowledge of meaning to other speakers, and the nature of such manifestations. If Dummett's argument is sound, then bivalence cannot be justified directly from semantics, and may not be justifiable at all.

PETER PAGIN

IRIGARAY, LUCE (1930–)

Luce Irigaray holds doctorates in both linguistics and philosophy, and has practised as a psychoanalyst for many years. Author of over twenty books, she has established a reputation as a pre-eminent theorist of sexual difference – a term she would prefer to 'feminist'. The latter carries with it the history of feminism as a struggle for equality, whereas Irigaray sees herself more as a feminist of difference, emphasizing the need to differentiate women from men over and above the need to establish parity between the sexes.

Speculum de l'autre femme (1974) (Speculum of the Other Woman) (1985), the book that earned her international recognition, fuses philosophy with psychoanalysis, and employs a lyrical 'mimesis', or mimicry, that parodies and undercuts philosophical pretensions to universality. While adopting the standpoint of universality, objectivity and uniformity, the philosophical tradition in fact reflects a partial view of the world, one which is informed by those largely responsible for writing it: men. Without the material, maternal and nurturing succour provided by women as mothers and homemakers, men would not have had the freedom to reflect, the peace to think, or the time to write the philosophy that has shaped our culture. As such, women are suppressed and unacknowledged; femininity is the unthought ground of philosophy – philosophy's other.

TINA CHANTER

ISLAMIC PHILOSOPHY

Introduction

Islamic philosophy may be defined in a number of different ways, but the perspective taken here is that it represents the style of philosophy produced within the framework of Islamic culture. This description does not suggest that it is necessarily concerned with religious issues, nor even that it is exclusively produced by Muslims.

ISLAMIC PHILOSOPHY

1 The early years of Islamic philosophy

Islamic philosophy is intimately connected with Greek philosophy, although this is a relationship which can be exaggerated. Theoretical questions were raised right from the beginning of Islam, questions which could to a certain extent be answered by reference to Islamic texts such as the Qur'an, the practices of the community and the traditional sayings of the Prophet and his Companions. On this initial basis a whole range of what came to be known as the Islamic sciences came to be produced, and these consisted largely of religious law, the Arabic language and forms of theology which represented differing understandings of Islam.

The early conquests of the Muslims brought them into close contact with centres of civilization heavily influenced by Christianity and Judaism, and also by Greek culture. Many rulers wished to understand and use the Greek forms of knowledge, some practical and some theoretical, and a large translation project started which saw official support for the assimilation of Greek culture. This had a powerful impact upon all areas of Islamic philosophy. Neoplatonism definitely became the prevalent school of thought, following closely the curriculum of Greek (Peripatetic) philosophy which was initially transmitted to the Islamic world. This stressed agreement between Plato and Aristotle on a range of issues, and incorporated the work of some Neoplatonic authors. A leading group of Neoplatonic thinkers were the Ikhwan al-Safa' (Brethren of Purity), who presented an eclectic philosophy designed to facilitate spiritual liberation through philosophical perfection. However, there was also a development of Aristotelianism in Islamic philosophy, especially by those thinkers who were impressed by the logical and metaphysical thought of Aristotle, and Platonism was inspired by the personality of Socrates and the apparently more spiritual nature of Plato as compared with Aristotle. There were even thinkers who seem to have been influenced by Greek scepticism, which they turned largely against religion, and Ibn ar-Rawandi and Muhammad ibn Zakariyya' al-Razi presented a thoroughgoing critique of many of the leading supernatural ideas of Islam.

Al-Kindi is often called the first philosopher of the Arabs, and he followed a broadly Neoplatonic approach. One of the earliest of the philosophers in Baghdad was in fact a Christian, Yahya Ibn 'Adi, and his pupil AL-FARABI created much of the agenda for the next four centuries of work. Al-Farabi argued that the works of Aristotle raise important issues for the understanding of the nature of the universe, in particular its origination. Aristotle suggested that the world is eternal, which seems to be in contradiction with the implication in the Qur'an that God created the world out of nothing. Al-Farabi used as his principle of creation the process of emanation, the idea that reality continually flows out of the source of perfection, so that the world was not created at a particular time. He also did an enormous amount of work on Greek logic, arguing that behind natural language lies logic, so that an understanding of the latter is a deeper and more significant achievement than a grasp of the former. This also seemed to threaten the significance of language, in particular the language – Arabic – in which God transmitted the Qur'an to the Prophet Muhammad. A large school of thinkers was strongly influenced by al-Farabi, including al-'Amiri, al-Sijistani and al-Tawhidi, and this surely played an important part in making his ideas and methodology so crucial for the following centuries of Islamic philosophy.

IBN SINA went on to develop this form of thought in a much more creative way, and he presented a view of the universe as consisting of entirely necessitated events, with the exception of God. This led to a powerful reaction from AL-GHAZALI, who in his critique of Peripatetic philosophy argued that it was both incompatible with religion, and also invalid on its own principles. He managed to point to some of the major difficulties with the developments of Neoplatonism which had taken place in Islamic philosophy, and he argued that while philosophy should be rejected, logic as a conceptual tool should be retained. This view became very influential in much of the Islamic world, and philosophy came under a cloud until the nineteenth century.

2 Philosophy in Spain and North Africa

A particularly rich blend of philosophy flourished in al-Andalus (the Islamic part of the Iberian peninsula), and in North Africa. Ibn Masarra defended a form of mysticism, and this type of thinking was important for both IBN TUFAYL and Ibn Bajja, for whom the contrast between the individual in society and the individual who primarily relates to God became very much of a theme. The argument was often that a higher level of understanding of reality can be attained by those prepared to develop their religious consciousness outside of the frame-

work of traditional religion, a view which was supported and became part of a highly sophisticated account of the links between religion and reason as created by Ibn Rushd. He set out to defend philosophy strenuously from the attacks of al-Ghazali, and also to present a more Aristotelian account than had been managed by Ibn Sina. He argued that there are a variety of routes to God, all equally valid, and that the route which the philosopher can take is one based on the independent use of reason, while the ordinary member of society has to be satisfied with the sayings and obligations of religion. Ibn Sab'in, by contrast, argued that Aristotelian philosophy and logic were useless in trying to understand reality since those ideas fail to mirror the basic unity which is implicit in reality, a unity which stems from the unity of God, and so we require an entirely new form of thinking which is adequate to the task of representing the oneness of the world. A thinker better known perhaps for his work on history and sociology than in philosophy is Ibn Khaldun, who was none the less a significant philosophical writer; he presents an excellent summary of preceding philosophical movements within the Islamic world, albeit from a conservative (Ash'arite) point of view.

3 Mystical philosophy

Mystical philosophy in Islam represents a persistent tradition of working philosophically within the Islamic world. Some philosophers managed to combine mysticism with Peripatetic thought, while others saw mysticism as in opposition to Peripateticism. Al-Ghazali had great influence in making mysticism in its Sufi form respectable, but it is really other thinkers such as al-Suhrawardi and Ibn al-'Arabi who produced actual systematic mystical thought. They created, albeit in different ways, accounts of how to do philosophy which accord with mystical approaches to reality, and which self-consciously go in opposite directions to Peripateticism. Ibn al-'Arabi concentrated on analysing the different levels of reality and the links which exist between them, while al-Suhrawardi is the main progenitor of Illuminationist philosophy. This tries to replace Aristotelian logic and metaphysics with an alternative based on the relationship between light as the main principle of creation and knowledge, and that which is lit up – the rest of reality. This tradition has had many followers, including al-Tusi, Mulla Sadra, Mir Damad and al-Sabzawari, and has been popular in the Persian world right up to today. Shah Wali Allah extended this school of thought to the Indian subcontinent.

4 Islamic philosophy and the Islamic sciences

Islamic philosophy has always had a rather difficult relationship with the Islamic sciences, those techniques for answering theoretical questions which are closely linked with the religion of Islam, comprising law, theology, language and the study of the religious texts themselves. Many theologians such as Ibn Hazm, al-Juwayni and Fakhr al-Din al-Razi presented accounts of Islamic theology which argued for a particular theory of how to interpret religious texts. They tended to advocate a restricted approach to interpretation, rejecting the use of analogy and also the idea that philosophy is an objective system of enquiry which can be applied to anything at all. Most theologians were Ash'arites, which meant that they were opposed to the idea that ethical and religious ideas could be objectively true. What makes such ideas true, the Ash'arites argued, is that God says that they are true, and there are no other grounds for accepting them than this. This had a particularly strong influence on ethics, where there was much debate between objectivists and subjectivists, with the latter arguing that an action is just if and only if God says that it is just. Many thinkers wrote about how to reconcile the social virtues, which involve being part of a community and following the rules of religion, with the intellectual virtues, which tend to involve a more solitary lifestyle. Ibn Miskawayh and Al-Tusi developed complex accounts of the apparent conflict between these different sets of virtues.

Political philosophy in Islam looked to Greek thinkers for ways of understanding the nature of the state, yet also generally linked Platonic ideas of the state to Qur'anic notions, which is not difficult given the basically hierarchical nature of both types of account. Even thinkers attracted to Illuminationist philosophy such as al-Dawani wrote on political philosophy, arguing that the structure of the state should represent the material and spiritual aspects of the citizens. Through a strict differentiation of role in the state, and through leadership by those skilled in religious and philosophical knowledge, everyone would find an acceptable place in society and scope for spiritual perfection to an appropriate degree.

Particular problems arose in the discussions concerning the nature of the soul. According to the version of Aristotle which was generally used by the Islamic philosophers, the soul is an integral part of the person as its form, and once the individual dies the soul disappears also. This appears to contravene the notion of an afterlife which is so important a part of Islam. Even Platonic views of the soul seem to insist on its spirituality, as compared with the very

physical accounts of the Islamic afterlife. Many of the philosophers tried to get around this by arguing that the religious language discussing the soul is only allegorical, and is intended to impress upon the community at large that there is a wider context within which their lives take place, which extends further than those lives themselves. They could argue in this way because of theories which presented a sophisticated view of different types of meaning that a statement may have in order to appeal to different audiences and carry out a number of different functions. Only the philosopher really has the ability to understand this range of meanings, and those who work in the Islamic sciences do not know how to deal with these issues which come outside of their area of expertise. While those skilled in dealing with the law will know how to adjudicate between different legal judgments, we need an understanding of the philosophy of law in Islam if we are to have access to what might be called the deep structure of law itself. Similarly, although the Qur'an encourages its followers to discover facts about the world, it is through the philosophy of science that we can understand the theoretical principles which lie behind that physical reality.

Many of the problems of religion versus philosophy arose in the area of aesthetics. The rules of poetry which traditionally existed in the Arabic tradition came up against the application of Aristotle's *Poetics* to that poetry. One of the interesting aspects of Islamic aesthetics is that it treated poetry as a logical form, albeit of a very low demonstrative value, along the continuum of logical forms which lie behind all our language and practices. This is explained in studies of both epistemology and logic. Logic came to play an enormous role in Islamic philosophy, and the idea that logic represents a basic set of techniques which lies behind what we think and what we do was felt to be very exciting and provocative. Many theologians who attacked philosophy were staunch defenders of logic as a tool for disputation, and Ibn Taymiyya is unusual in the strong critique which he provided of Aristotelian logic. He argued that the logic entails Aristotelian metaphysics, and so should be abandoned by anyone who wishes to avoid philosophical infection.

However, the general respect for logic provides the framework for the notion that there is a range of logical approaches which are available to different people, each of which is appropriate to different levels of society. For the theologian and the lawyer, for instance, dialectic is appropriate, since this works logically from generally accepted propositions to conclusions which are established as valid, but only within the limits set by those premises. This means that within the context of theology, for example, if we accept the truth of the Qur'an, then certain conclusions follow if we use the principles of theology; but if we do not accept the truth of the Qur'an, then the acceptability of those conclusions is dubious. Philosophers are distinguished from everyone else in that they are the only people who use entirely certain and universal premises, and so their conclusions have total universality as well as validity. When it comes to knowledge we find a similar contrast. Ordinary people can know something of what is around them and also of the spiritual nature of reality, but they are limited to the images and allegories of religion and the scope of their senses. Philosophers, by contrast, can attain much higher levels of knowledge through their application of logic and through their ability to perfect their understanding and establish contact with the principles which underlie the whole of reality.

5 Islamic philosophy in the modern world

After the death of Ibn Rushd, Islamic philosophy in the Peripatetic style went out of fashion in the Arab world, although the transmission of Islamic philosophy into Western Europe started at this time and had an important influence upon the direction which medieval and Renaissance Europe were to take. In the Persian-speaking world, Islamic philosophy has continued to follow a largely Illuminationist curriculum right up to today; but in the Arab world it fell into something of a decline, at least in its Peripatetic form, until the nineteenth century. Mystical philosophy, by contrast, continued to flourish, although no thinkers matched the creativity of Ibn al-'Arabi or Ibn Sab'in. Al-Afghani and Muhammad 'Abduh sought to find rational principles which would establish a form of thought which is both distinctively Islamic and also appropriate for life in modern scientific societies, a debate which is continuing within Islamic philosophy today. Iqbal provided a rather eclectic mixture of Islamic and European philosophy, and some thinkers reacted to the phenomenon of modernity by developing Islamic fundamentalism. This resuscitated the earlier antagonism to philosophy by arguing for a return to the original principles of Islam and rejected modernity as a Western imperialist instrusion. The impact of Western scholarship on Islamic philosophy has not always been helpful, and Orientalism has sometimes led to an overemphasis of the dependence of Islamic philosophy on Greek thought, and to a refusal to regard Islamic philosophy as real philosophy. That is, in much of the exegetical literature there has been too much concern dealing with the historical conditions

under which the philosophy was produced as compared with the status of the ideas themselves. While there are still many disputes concerning the ways in which Islamic philosophy should be pursued, as is the case with all kinds of philosophy, there can be little doubt about its major achievements and continuing significance.

J

JAINA PHILOSOPHY

The issues in Jaina philosophy developed concurrently with those that emerged in Buddhist and Hindu philosophy. The period from the second century BC to about the tenth century AD evinces a tremendous interaction between the schools of thought and even an exchange of ideas, borne out especially in the rich commentary literature on the basic philosophical works of the respective systems. Jaina philosophy shares with Buddhism and Hinduism the aim of striving, within its own metaphysical presuppositions, for absolute liberation (*mokṣa* or *nirvāṇa*) from the factors which bind human existence. For the philosophical systems of Indian thought, ignorance (of one's own nature, of the nature of the world and of one's role in the world) is one of the chief such factors, and Jainism offers its own insights into what constitutes the knowledge that has the soteriological function of overcoming ignorance. Jainism is not exempt from the problem of distinguishing the religious and/or mystical from the 'philosophical'; the Indian tradition has no exact equivalents for these categories as they are usually employed in Western thought.

The significance ascribed to knowledge is reflected in the attention given to epistemology and logic by Jaina philosophers. The first systematic account was given by the fourth- or fifth-century philosopher Umāsvāti, who distinguished two types of knowledge: partial knowledge, which is obtained from particular standpoints, and comprehensive knowledge, which is of five kinds – sensory knowledge, scriptural knowledge, clairvoyance, telepathy and omniscience. Of these, the first two are held to be indirect (consisting in, or analogous to, inference) and the remainder are direct; Jainism is unique among Indian philosophies in characterizing sensory knowledge as indirect. The aim of the treatises on knowledge is to present what the Jainas believe would be known in the state of omniscience, as taught by Mahāvīra. Omniscience is an intrinsic condition of all souls; however, due to the influence of karma since beginningless time this essential quality of the soul is inhibited.

The Jaina interest in logic arose, as with the other schools, through a consideration of inference as a mode of knowledge. The methods and terminology of the Nyāya school were heavily drawn upon; this is evident in Siddhasena Divākara's *Nyāyāvatāra* (The Descent of Logic) (*c.* fifth century), one of the first detailed presentations of Jaina logic. The Jainas used logic to criticize other schools and defend their own. The acquaintance with other traditions that this implies is a notable aspect of classical Jainism; their interest in other schools, coupled with their belief in collecting and preserving manuscripts, makes the Jaina corpus very important for the study of classical Indian thought.

According to Jaina ontology, reality is divided into the two basic principles of sentience and non-sentience, neither of which is reducible to the other. The former is manifested in souls, of which there are an infinite number, and the latter in the five basic substances, which are matter, *dharma* and *adharma* (factors posited to explain movement and rest), space and time. Matter consists of atoms; as it becomes associated with the soul, it gets attached to it, becomes transformed into karma and thereby restricts the functions of consciousness. This pernicious process can only be reversed through ascetic practices, which ultimately lead to liberation.

Ascetic practices constitute the basis of Jaina ethics, the framework of which are the 'five great vows', according to which the ascetics vow to live. These are: nonviolence towards all forms of life, abstinence from lying, not taking what is not given, celibacy and renunciation of property. Nonviolence is strongly emphasized, since violence produces the greatest amount of karma. Hence great care has to be exercised at all times, especially because injury of life forms should be avoided also in plants, water, fire, etc. The minimization of physical activity to avoid injury is therefore an important ideal of Jaina asceticism. Inspiration for constant ethical behaviour is provided by a contemplation of the lives of the twenty-four Jinas, of whom Mahāvīra was the last. Though human, these 'conquerors of the passions' are worshipped as divine beings because

of their conduct in the world and knowledge of the nature of ultimate reality.

JAYANDRA SONI

JAMES, WILLIAM (1842–1910)

The American William James was motivated to philosophize by a desire to provide a philosophical ground for moral action. Moral effort presupposes that one has free will, that the world is not already the best of all possible worlds, and, for maximum effort, according to James, the belief that there is a God who is also on the side of good.

In his famous, often misunderstood paper 'The Will to Believe', James defended one's right to believe in advance of the evidence when one's belief has momentous consequences for one's conduct and success, and a decision cannot be postponed. One such belief is the belief in objective values. Generally, a belief is objective if it meets a standard independent of the believer's own thought. In morals, objective values emerge from each person's subjective valuings, whatever their psychological source, when these valuings become the values of a community of persons who care for one another. Still, even in such a community there will be conflicting claims, and the obligations generated by these claims will need to be ranked and conflicts resolved. James' solution is to say that the more inclusive claim – the claim that can be satisfied with the lesser cost of unsatisfied claims – is to be ranked higher. This is not to be mistaken for utilitarianism: James is not a hedonist, and it is not clear what he means by the most inclusive claim.

A concern for others makes sense only if there are others who inhabit with us a common world. Pragmatism, which he co-founded with C.S. Peirce, and radical empiricism provide James' answer to those who would be sceptics concerning the existence of the common-sense world. Pragmatism is both a theory of meaning and a theory of truth. As a theory of meaning it aims at clarity; our thoughts of an object are clear when we know what effects it will have and what reactions we are to prepare. As a theory of truth, pragmatism makes clear what is meant by 'agreement' in the common formula that a belief is true if it agrees with reality. Only in the simplest cases can we verify a belief directly – for example, we can verify that the soup is too salty by tasting it – and a belief is indirectly verified if one acts on it and that action does not lead to unanticipated consequences. Contrary to a widespread misunderstanding, this does not mean that James defines truth as that which is useful; rather, he points out that it is, in fact, useful to believe what is true.

James rejects the dualism of common sense and of many philosophers, but he is neither a materialist nor an idealist, rather what he calls a 'pure experience' (for example, your seeing this page) can be taken as an event in your (mental) history or as an event in the page's (physical) history. But there is no 'substance' called 'pure experience': there are only many different pure experiences. You and I can experience the same page, because an event in your mental history and an event in mine can be taken to be events in the same physical history of the page; James may even have been tempted to say that a pure experience can be taken to belong to more than one mental history.

According to James, pragmatism mediates the so-called conflict between science and religion. James took religious experiences very seriously both from a psychologist's perspective and as evidence for the reality of the divine.

RUTH ANNA PUTNAM

JAPANESE PHILOSOPHY

Introduction

The most distinctive characteristic of Japanese philosophy is how it has assimilated and adapted foreign philosophies to its native worldview. As an isolated island nation, Japan successfully resisted foreign invasion until 1945 and, although it borrowed ideas freely throughout its history, was able to do so without the imposition of a foreign military or colonial presence. Japanese philosophy thus bears the imprint of a variety of foreign traditions, but there is always a distinctively Japanese cultural context. In order to understand the dynamics of Japanese thought, therefore, it is necessary to examine both the influence of various foreign philosophies through Japanese history and the underlying or continuing cultural orientation that set the stage for which ideas would be assimilated and in what way.

The major philosophical traditions to influence Japan from abroad have been Confucianism, Buddhism, neo-Confucianism and Western philosophy. Daoism also had an impact, but more in the areas of alchemy, prognostication and folk medicine than in philosophy. Although these traditions often overlapped, each also had distinctive influences.

In its literary forms, Japanese philosophy began about fourteen centuries ago. Confucian thought entered Japan around the fifth century AD. Through the centuries the imprint of Confucianism has been most noticeable in the areas of social structure, government organization and ethics. Philosophically speaking, the social self in Japan has its roots mainly in Confucian ideals, blended since the sixteenth century with certain indigenous ideas of loyalty and honour developed within the Japanese *samurai* or warrior class.

The philosophical impact of Buddhism, introduced around the same time as Confucianism, has been primarily in three areas: psychology, metaphysics and aesthetics. With its emphasis on disciplined contemplation and introspective analysis, Buddhism has helped define the various Japanese senses of the inner, rather than social, self. In metaphysics, Buddhist esotericism has been most dominant; through esoteric Buddhist philosophy, the Japanese gave a rational structure to their indigenous beliefs that spirituality is immanent rather than transcendent, that mind and body (like humanity and nature) are continuous rather than separate, and that expressive power is shared by things as well as human thought or speech. This metaphysical principle of expression has combined with the introspective psychology and emphasis on discipline to form the foundation of the various aesthetic theories that have been so well developed in Japanese history.

Neo-Confucianism became most prominent in Japan in the sixteenth century. Like classical Confucianism, it contributed much to the Japanese understanding of virtue and the nature of the social self. Unlike classical Confucianism in Japan, however, neo-Confucianism also had a metaphysical and epistemological influence. Its emphasis on investigating the principle or configuration of things stimulated the Japanese study of the natural world. This reinforced a tendency initiated with the very limited introduction of Western practical sciences and medicine in the sixteenth century.

Western philosophy, along with Western science and technology, has had its major impact in Japan only since the middle of the nineteenth century. The process of modernization forced Japanese philosophers to reconsider fundamental issues in epistemology, social philosophy and philosophical anthropology. As it has assimilated Asian traditions of thought in the past – absorbing, modifying and incorporating aspects into its culture – so Japan has been consciously assimilating Western thought since the early twentieth century. The process continues today.

What in all this is distinctively Japanese? On the superficial level, it might seem that Japan has drawn eclectically from a variety of traditions without any inherent sense of intellectual direction. A more careful analysis, however, shows that Japanese thinkers have seldom adopted any foreign philosophy without simultaneously adapting it. For example, the Japanese philosophical tradition never fully accepted the emphasis on propriety or the mandate of heaven so characteristic of Chinese Confucianism. It rejected the Buddhist idea that impermanence is a reality to which one must be resigned, and instead made the appreciation of impermanence into an aesthetic. It criticized the neo-Confucian and Western philosophical tendencies toward rationalism and positivism, even while accepting many ideas from those traditions. In short, there has always been a complex selection process at work beneath the apparent absorption of foreign ideas.

Both historically and in the present, some Japanese philosophers and cultural critics have tried to identify this selection process with Shintō, but Shintō itself has also been profoundly shaped by foreign influences. The selection process has shaped Shintō as much as Shintō has shaped it. In any case, we can isolate a few axiological orientations that have seemed to persist or recur throughout the history of Japanese thought. First, there has been a tendency to emphasize immanence over transcendence in defining spirituality. Second, contextual pragmatism has generally won out over attempts to establish universal principles that apply to all situations. Third, reason has often been combined with affect as the basis of knowledge or insight. Fourth, theory is seldom formulated in isolation from a praxis used to learn the theory. Fifth, although textual authority has often been important, it has not been as singular in its focus as in many other cultures. Thus, the Japanese have not typically identified a single text such as the Bible, the *Analects*, the Qur'an or the *Bhagavad Gītā* as foundational to their culture. Although there have been exceptions to these general orientations, they do nonetheless help define the broader cultural backdrop against which the drama of Japanese philosophy has been played out through history.

1 Archaic spirituality

The earliest accounts of Japan by Chinese visitors, archaeological remains of the prehistoric culture and the earliest recorded prayers and songs all suggest that Japan was originally an animistic culture with shamanistic qualities. The world was understood to be full of *kami*, sacred presences in the form of awe-inspiring natural objects, personal deities, ghosts and clannish guardian spirits. The ancient rituals were apparently designed for appeasing the *kami* so that humans might live in harmony with them and benefit from their powers. The early poems, recorded in such court-sponsored compilations as the *Man'yōshū*, indicate an internal relationship between humanity and nature. That is, the ancients understood humanity and nature to be parts of each other, not independently existing entities related as subject and object. The ancient myths describe the creation of Japan through the fortuitous actions of the deities. For this reason, the world is infused with *kami* or sacred presence.

According to the myths, natural objects such as rocks and streams were originally endowed with speech, a power taken from them because of their noisy bickering and querulous nature. Although natural things lost their voice, they did not necessarily lose their expressiveness. Human beings, if properly attuned to the natural world, could voice that expressiveness in thoughts, words and artefact. In ancient Japanese, the term for this expressive possibility was *kotodama*, the 'spirit' (*dama*) of 'word' (*koto*) and/or 'thing' (also *koto*).

In short, the ancient Japanese worldview understood the gods, the natural world and humanity to be an ontological continuum. It is not precise to say that rocks and trees were the dwelling place of spirits, because that would establish a bifurcation between the spiritual and material instead of a continuity. The term *kami*, therefore, applied to any object where a sacred presence was particularly manifest or concentrated: the Sun Goddess Amaterasu, Mount Fuji, a special tree or waterfall, the emperor or the vengeful spirit of a fallen warrior. Even the sword of that warrior might be treated as *kami*. This represents one enduring idea in Japanese culture, the emphasis on spiritual immanence instead of transcendence: the sacred permeates the everyday world.

2 The importation of Confucianism and Buddhism

The Chinese writing system was introduced into Japan at about the beginning of the fifth century AD, but it was not until the eighth century that a viable adaptation was devised for rendering Japanese in written form. Therefore early Japanese thought was expressed in Chinese, and in fact many philosophical intellectuals continued to write in Chinese (or a Japanized version of Chinese) as late as the nineteenth century.

When the Chinese writing system was first introduced, the various clans had begun to form a central government under the leadership of what would become the imperial family. The government coalesced in Yamato, a large plain adjoining what is today Kyoto, Nara and Osaka. With the introduction of Chinese literacy, the Japanese elite gained access to more than a millennium of Confucian and Buddhist philosophy. These ideas were immediately put to use in organizing the state.

Confucianism gave Japan a hierarchical model for social and political order. It focused on personal interaction, explaining the responsibilities and duties relevant to the five basic dyadic relations: master–servant, parent–child, husband–wife, elder sibling–younger sibling and friend–friend. When the dyadic relationships are hierarchical, the person in the superior position is to care for the person in the lower and the person in the lower position is to be loyal to the superior. The imperial family used this system to institute a vertical bureaucracy. Although Confucianism supplied a social structure to the state, the ancient Japanese showed little interest in developing Confucian philosophy *per se*.

Buddhism, on the other hand, was initially most attractive to the Japanese for its aesthetic and thaumaturgic qualities. Buddhist artisans, often immigrants from Korea, brought new techniques of grand architecture, painting, sculpture and music. Using these elegant accoutrements in its rituals for healing, prosperity and protection of the state, Buddhism sometimes competed with the indigenous religious practices addressed to the *kami*.

From the philosophical perspective, however, the most important impact of Buddhism was its psychology. Through its meditative techniques and advanced analyses of the human predicament, Buddhism heightened the Japanese awareness of the workings of heart and mind. Buddhism teaches

that egoism is the primary cause of human anguish and dissatisfaction. The ego seeks permanence and control in a world of continuing flux. By controlling the desires and eliminating egoism, one can achieve peace and inner harmony. These Buddhist teachings brought a dimension of inner awareness and psychological analysis to a culture that had formerly operated only within the concepts of taboo, purification and animistic appeasement (see BUDDHIST PHILOSOPHY, JAPANESE).

At the same time, the indigenous religion began to define itself in relation to its rival, Buddhism. It took the name *kami no michi* or *shintō*, the 'way of the *kami*'. The state helped to systematize a series of myths in the eighth century, explaining the relationships among the tutelary *kami* of the various powerful clans and, presumably, the political relationships among the clans themselves. Most critically, through its familial relation with the chief *kami*, the Sun Goddess Amaterasu, the throne established itself as the blood tie between the celestial *kami* and the Japanese people (see SHINTŌ).

A major goal of philosophy in the seventh and eighth centuries, therefore, was to integrate the available ideas, both foreign and native, into a systematic worldview in the service of political stability. In this light the Seventeen Article Constitution of AD 604 is one of the first philosophical documents of ancient Japan. Attributed to Prince Shōtoku (574–622), the Constitution is really more a set of guidelines for bureaucrats than a set of laws defining political structure. In it, however, we find the early impact of Chinese thinking and its adaptation to the Japanese context of the time.

The Constitution's first article opened with a quotation from CONFUCIUS about the importance of maintaining 'harmony'. As noted already, in traditional Confucianism one achieves harmony primarily through performing actions appropriate to one's relationships in the society. Rather than discussing such Confucian principles, however, a large portion of the Constitution discussed human frailty and the need to develop a sympathetic attitude. The Constitution admonished against hypocrisy, preferential treatment, envy and egocentric motives. On the positive side, it advocated consensus and open-mindedness. In short, while the document aimed for a harmonious Confucian social order, it also drew on Buddhist psychology to explain the obstacles to harmony and to suggest an introspective understanding of personal motivations. Although the Constitution itself lacked any detailed philosophical argument, it marks an early attempt to draw on multiple philosophical traditions in a coherent manner. In effect, it advocated a Confucian social and government order supported by Buddhist practice and the insights of Buddhist psychology. This philosophy of government remained dominant in Japan for at least a millennium.

In the Nara period (710–94), Japanese scholar-monks secured court support to accumulate and study more texts in Buddhist philosophy. They organized themselves loosely around major traditions from the mainland, and became the Six Nara Schools of Buddhism: Ritsu, Kusha, Jōjitsu, Hossō, Sanron and Kegon (see BUDDHIST PHILOSOPHY, JAPANESE). The first primarily concentrated on the study of Vinaya, the precepts and regulations for ordering monastic life. The Kusha and Jōjitsu were schools of Abhidharma Buddhism emphasizing the detailed analysis of dharmas, the basic constituents of reality or consciousness. The Hossō was primarily based in the Indian Yogācāra tradition and Sanron in the Mādhyamika. Kegon represented the tradition known in China as Huayan. Although the Six Nara Schools played an important role in both education and court politics, there is little evidence that they were philosophically creative centres. Their historical role was mainly to introduce Buddhist analysis and doctrine into Japanese culture. They provided the intellectual raw material for the later philosophical developments of the Heian period.

3 Metaphysical vision of ancient Japanese esoteric Buddhism

Although already a significant presence in the Nara period, only in the Heian period (794–1185) did Buddhism undergo a profound process of philosophical development and Japanization. Two Buddhist thinkers were particularly influential: KŪKAI (774–835; posthumous title, Kōbō Daishi) and Saichō (767–822; posthumous title, Dengyō Daishi). Of the two, Kūkai's philosophical contribution was the more comprehensive. He went to China in 804 to study esoteric Buddhism and, upon his return two years later, founded Japanese Shingon Buddhism. The analytic and systematic character of Kūkai's writings may well qualify him as the first true philosopher in Japanese history.

For Kūkai, reality is fundamentally a person. The entire cosmos is no more than the thoughts, words and deeds of the Buddha called Dainichi (literally the 'Great Sun'). Dainichi is not the creator of the universe; Dainichi is the universe. In a perpetual state of enlightened meditation, Dainichi performs the three great practices of esoteric Buddhism: the chanting of sacred syllables (*mantras*), the visualization of geometrical arrays of symbols (*mandalas*) and the performance of sacred postures or hand gestures (*mudras*). These three activities define the nature of the universe. The *mantras* are microcosmic resonances or vibrating states of matter–energy that constitute the basic elements. The *mandalas* define

the essential structure, and the *mudras* constitute the patterns of change. By performing the rituals of *mantra*, *mandala* and *mudra*, a person achieves immediate insight into the nature of the cosmos. By introspection on the nature of their own thoughts, words and deeds, the Shingon Buddhist is said to achieve insight into the thoughts, words and deeds of the Buddha, Dainichi. By understanding one's own person, one understands the person that is all of reality.

Within the framework of this metaphysical system, Kūkai developed a comprehensive philosophy addressing several major philosophical issues. For example, he criticized the idea that insight or enlightenment could be purely mental or intellectual. Because the universe itself consists of thought, word and deed (or structure, resonance and patterned change), it can only be grasped by unified praxis of the whole person: mind, speech and body. To know reality is to participate in it fully, in all three of its dimensions.

Another philosophical issue of interest to Kūkai was the nature of expression. Because the cosmos is a person, reality is the expressive style of that person. Every entity is, therefore, a symbol or imprint of Dainichi's mental, somatic and verbal activity. Yet, because we contain the element of volitional consciousness, we humans can also ignore the true source of all activity, construing ourselves as independent entities. We can interpret things through the superimposition of our own imprints, covering over their (and our) more fundamental nature. This delusion is the source of human anguish and ignorance. The escape from delusion lies in recognizing and participating in the self-expressive nature of reality.

Kūkai's contemporary and major competitor, Saichō, founded Japanese Tendai Buddhism. Although Saichō's primary goal in visiting China was to bring back to Japan the teaching of the Tiantai Buddhist tradition (see Buddhist philosophy, Chinese), he also had a chance encounter with a teacher of esotericism. When he returned to Japan, therefore, his Tendai school incorporated esoteric Buddhist elements as well as exoteric Tiantai teachings. Through the exchange of Shingon and Tendai disciples in Japan, some of Kūkai's esoteric teachings also found their way into Tendai. The result was that by the end of the ninth century, the two dominant forms of Japanese Buddhism were both at least partially esoteric in nature.

We can explain the influence of the esoteric Buddhist theory of reality from both the standpoint of cultural history and the history of philosophy. Culturally, it is important that esoteric Buddhism did not either doctrinally or politically oppose the presence of the indigenous religion, Shintō. Esoteric Buddhism reinforced rather than challenged many aspects of the indigenous religious worldview: the ubiquity of the sacred, the expressiveness of nature and the nonduality of matter and spirit, for example. Furthermore, both Kūkai and Saichō correlated the various buddhas of esotericism with the various *kami* of the traditional Japanese religion. By this process, Japanese archaism was, in effect, defended by a philosophically sophisticated system of Buddhist thought imported from the mainland and adapted to the Japanese context. Buddhism and Shintō could therefore be practised alongside each other without contradiction.

This development set the metaphysical backdrop against which later Japanese thought would develop. One might say that esoteric Buddhism did for Japanese philosophy what Plato and Aristotle did for Western philosophy. It laid out a set of assumptions and a *Problematik* that had a profound influence on the thought to follow. Two assumptions were particularly influential.

First, esotericism has a distinctive view of the relation between part and whole. The whole is recursively manifest or reflected in the part. It is not that the parts constitute the whole nor that the whole is more than the sum of its parts; rather, since the part is what it is by virtue of the whole, if we truly understand the part, we find the whole imprinted in it. In Shingon's case, for example, since any individual thing is an expression of the cosmos as Dainichi, when we truly understand the part (the individual thing), we encounter the whole (Dainichi) as well.

With this orientation as a cultural presupposition, later Japanese philosophers would seldom endorse either atomistic analysis or individualism (see Atomism, ancient; Methodological individualism). Atomistic analysis had been introduced into Japan via the Nara Schools of Jōjitsu and Kusha. Kūkai explicitly ranked them as philosophical 'mindsets' far below Kegon and Tendai, in part because only the latter endorsed this theory of whole-as-part. Individualism, with attendant theories of social contract, entered Japan via the West only in the late nineteenth century. Since it viewed the social whole as constituted by the parts, it ran counter to this esoteric assumption. Not surprisingly, individualism has never taken hold in Japan as a basis for social, ethical or political theory.

Second, esotericism's metaphysics argued that reality is self-expressive. Human beings are, of course, part of reality. When humans speak authentically or truly, therefore, they do not refer to reality, but rather are part of its self-expression. This position undermines any philosophical tendencies toward idealism (reality as a production of

mind), realism (reality as pre-existing our expressions and truth as matching our expressions with that reality) or radical nominalism (expressions refer primarily to other expressions without necessary connection to non-linguistic reality) (see IDEALISM; REALISM AND ANTIREALISM; NOMINALISM). In the Nara Schools there were variants of idealism (Hossō), realism (Kusha and Jōjitsu) and nominalism (Sanron). Again Kūkai ranked them all below Kegon and Tendai, and certainly below what he believed to be the only comprehensive mind-set, esotericism.

This presupposition about the self-expressive nature of reality underlies most Japanese aesthetic theories as well. The Heian period was the first to develop a detailed set of aesthetic terms, for example, *miyabi* (cultured, refined elegance) and *mono no aware* (the 'ah-ness of things' or the aesthetic tinge of sadness arising from an appreciation of the evanescent). In later periods, other aesthetic terms such as *yūgen* (hidden sublimity or depth), *sabi* (the 'loneliness' of an elegance allowed to age) and *wabi* (rusticity) came to the fore. These terms have rich connotations not readily translated into English. In general, though, they signify equally a quality of the object and the response of the aesthete or artist. The aesthetic is understood to be a self-expressive resonance between the object and artist. The world expresses itself through the artist as the work of art.

4 *Medieval philosophical anthropology: Pure Land Buddhism*

During the Heian period the highly literate and elegant culture of the Kyoto court was at its peak. The aesthetically pleasing rituals of esoteric Buddhism found a receptive audience among the aristocrats and clergy. They alone enjoyed the leisure time, education and resources to devote their lives to its study and practice. The general populace were left to their folk religions, an amalgamation of practices with roots in Buddhism, Shintō and Daoist alchemy.

By the early twelfth century, the court had become so politically effete that the provincial aristocracy began to vie for power and the newly risen *samurai* fought for control of territory. Plagues, famines and earthquakes were also unusually devastating. In short, to any sensitive observer of the times, it was easy to see the decadence of the social order, the harshness of nature and the corruption of the human spirit. There was little time for, or consolation in, metaphysical speculations. The philosophers turned their analyses to this world and their imaginations to wondering what failing in humanity had caused such suffering. By 1185 the Minamoto clan was victorious and in 1192 Yoritomo became *shōgun*, establishing his centre of government in Kamakura. Thus began the Kamakura period (1185–1333) and a new set of philosophical and religious orientations.

The Kamakura period philosophers such as Hōnen (1133–1212), Shinran (1173–1262), Yōsai or Eisai (1141–1215), DŌGEN (1200–53) and Nichiren (1222–82) responded to the decay and suffering of their times. Each developed his own interpretation of the human predicament with an accompanying solution. All had originally trained as Tendai monks, but these reformers eventually left the establishment and founded new Buddhist sects that served the masses as well as the elite echelons of Japanese society. Of the Kamakura schools of Buddhism, Pure Land and Zen have been the most influential in their theories of human being. Shinran was the founder of Shin Buddhism or the True Pure Land School; Dōgen was the founder of Sōtō Zen. Each developed most fully the philosophical foundations for his own tradition (see BUDDHIST PHILOSOPHY, JAPANESE).

These two schools differ radically in their philosophical anthropologies. As Buddhists, both Shinran and Dōgen accepted the general Buddhist analysis about the source of ignorance: egoism. Egoism defines the self as an independent agent that initiates actions and has experiences. The Buddhist view, on the other hand, maintains that 'I' is no more than a name for related actions and events, not something that lies behind them. This implies that the boundaries of the self are fuzzy rather than sharply delineated. For example, from a distance we can readily identify the general course of a river, but if we move up close enough, we cannot specify exactly where the river ends and the river bank begins. If the river were self-conscious and tried to specify for itself 'my' boundaries as opposed to 'its' boundaries, the river would lose sight of the very processes that bring it into being and help define it. Analogously, Buddhists generally maintain that egoism, by attempting to define, delineate and protect the self, ignores the self's broader context. It overlooks the self's dependence on what egoism considers to be outside and separate from it.

As a disciple of Hōnen, the founder of the Japanese Pure Land School, Shinran also accepted the specific ideas of that tradition, including the theory that humanity had entered a degenerate period in history. Left to our own devices, we are presumed to be doomed to live and relive an existence of anguish, dissatisfaction and despair. Pure Land Buddhists believe, however, that a celestial buddha called Amida has seen our situation and taken pity on us. He has vowed that if we entrust ourselves totally to his compassion and call

on his name, we can be assured rebirth in his Pure Land where the conditions are conducive to Buddhist practice. In his Pure Land we can perform the necessary spiritual disciplines and then return to this world to attain enlightenment. In so doing, we can be a spiritual aid to others in this world. Such was the basic tradition of Pure Land Buddhism that Shinran accepted. Within that traditional framework, however, he developed his own distinctive philosophical analysis of human being.

Shinran believed he had found a contradiction in how most Buddhists understood practice. Specifically, they self-consciously undertook various disciplines (meditation, reading texts, chanting mantras) as a means of eliminating egoism and attaining insight into reality. The implication is that one can overcome egoism by one's own power, by 'self-power.' People believed they were 'earning merit' by their religious practices. Shinran argued that if people practise as a means of achieving merit, then the actions only feed, rather than eradicate, egoism: discipline is understood as a means by which *I* can improve *myself*. Shinran considered this emphasis on self-power to be the psychological foundation of the degenerate age in which he believed he lived. Because people misunderstood the relation between self and Buddhist practice, the teachings of Buddhism had indeed become unintelligible and the prospect for insight had disappeared.

Although Shinran did not explicitly deny the ontological reality of the Pure Land or the account of Amida's vow as historical, his philosophy focused more on the psychological and logical implications of the Pure Land position. For him the fundamental point was that people must surrender their egoistic senses of self by adopting an 'entrusting heart-and-mind' (*shinjin*). By completely abandoning the ego, people can have faith in the power of Amida's vow to help. They turn from 'self-power' to 'other-power'. Assured birth in the Pure Land, the realm devoid of egoism, the sense of a discrete or independent self will disappear. Yet, Shinran reasoned, if there is no self at that point, logically there can be no discrete 'other' either. There is just 'naturalness' and Amida in effect disappears as well. *Shinjin* continues as the entrusting that opens itself to this naturalness. In that egoless state, one can spiritually help other people. It can be said that one returns from the Pure Land to be reborn in this world. Yet, by assisting others in this world, the ego may once again be constituted as the 'I' who self-consciously helps 'others'. As soon as one begins to think that good deeds are done by virtue of one's own power, the whole process must be renewed. One must again see the delusion of the ego, again turn oneself over to Amida's power, again be reborn in the Pure Land, again allow self and Amida to disappear, and again return to this world from the Pure Land.

In short, Shinran agreed that to eliminate ignorance one must eliminate egoism. This can be accomplished, he believed, only by the complete renunciation of the notion that one can help oneself. Only by despairing of the efficacy of self-power and by entrusting oneself to Amida's power can one become naturally what one truly is. In that egoless state one can understand reality for what it is and act freely in the world as a compassionate being. In addressing the same issue, Zen Buddhism took an almost diametrically opposed approach, however.

5 Medieval philosophical anthropology: Zen Buddhism

Like the Pure Land Buddhists, Zen Master Dōgen believed there is a fundamental flaw in the usual interpretation of Buddhist practice as the means to enlightenment. Rather than arguing that practice must be abandoned, however, he instead maintained that practice or self-discipline is an end in itself. He rejected the popular theory that his was a degenerate age in which enlightenment was no longer possible. Instead, Dōgen maintained everyone is already enlightened, but that enlightenment was not being manifested or expressed in their actions. The goal, therefore, is to authenticate what we already are.

Trained in the Zen (Chan) Buddhist tradition in China, Dōgen was sensitive to the limitations of language and mistrustful of certain types of thinking. Like other Buddhists, he understood the problem to be egoism. By hypostatizing the ego, one falls into a desire for reality to be a specific way. One seeks permanence in both self and in one's own worldview. Therefore, it is easy to project interpretations on experience, interpretations that shape the experience to meet our presuppositions, expectations and desires.

Dōgen believed that experiential immediacy is possible. In Zen meditation, one quiets the mind and merely lets phenomena appear. Dōgen called this a state of 'without-thinking' as opposed to either 'thinking' or 'not-thinking'. Thinking, for Dōgen, included any form of sustained conceptualization whether fantasy, cogitation, believing, denying, wishing, desiring or whatever. Not-thinking is the effort to blank the mind and empty it of all awareness. In without-thinking, however, there is the awareness of brute phenomena but no sustained act of bestowing meaning. There is no consciousness of a self having an experience. Furthermore, since no meaning at all is projected on the event, it is free of the distortions found in ordinary, ego-driven forms of experience. Dōgen

simply called this 'the presencing of things as they are'.

Dōgen claimed this form of meditation was not a means to enlightenment. Instead, precisely because it is egoless, it is enlightenment itself. Yet, this meditation–enlightenment event is always accessible. It is, as it were, at the root of all experience, even thinking and not-thinking. In this respect we are all already enlightened but we have not authenticated that fact. Of course, to authenticate it, we must return to a state of without-thinking.

Without-thinking is, therefore, a not-yet-conceptualized immediacy. Since it is without concepts, however, it is intrinsically meaningless; but it is impossible for humans to live a life without meanings. Enlightenment must not only be authenticated in meditation. It must also be expressed in everyday life. How can this be possible?

Dōgen claimed that meaning is always contextual. He noted that the ocean has a different meaning to a fish swimming in it, a person in a boat out at sea and a deity looking down at it from the heavens. To the fish, the ocean is a translucent palace; to the person it is a great circle extending to the horizon in all directions; to the deity it is a string of jewel-like lights glittering in the sunshine. If the deity were to interpret the ocean as a circle or the person in the boat were to interpret it as a palace, however, they would not be expressing what is actually in front of them. Their interpretation would be false. Therefore, the key to truth in meaning is the appropriateness of the context.

According to Dōgen, meditative without-thinking is the 'touchstone' for determining whether the context is appropriate. Context is continually shifting and giving rise to new meanings as we live out our lives. What is 'tree branch' at one point may be 'firewood' at another and 'weapon' in a third. Dōgen referred to these points as 'occasions' of 'being-time'. For Dōgen, the problem with egoism is its resistance to accepting flux. Egoism tries to make a set of previous meanings into a fixed worldview, into *my* reality. Therefore, one projects contexts that are not actually present in the current phenomena. Through meditation, however, one can break the closed cycle of self-verifying projections. One can return to the presence of things as they are before meaning, before they are embedded in any particular context. Then, as one returns to the expressive world of everyday action, it is easier to verify the appropriateness of the contextualizing process that generates meaning (see Meaning and verification).

The philosophical anthropologies of Pure Land and Zen address the common problem of egoism, but their solutions to the problem are fundamentally different. In Pure Land Buddhism, recognizing the inefficacy of egoism leads to a psychodynamic of despair, entrusting and naturalness. In the Pure Land philosophy of human being, the ego is rejected in favour of a model of dependence or interdependence. It is a process of self-effacement and surrender. By contrast, Zen overcomes the negative effects of egoism not by self-effacement, but by self-analysis. One studies the dynamics of consciousness and grounds oneself in pure, but meaningless, presence. Pure Land and Zen agree that self-discipline is not a means to enlightenment. Yet, for Pure Land this entails the rejection of self-discipline; in Zen, on the other hand, it entails the acceptance of self-discipline as an end in itself.

These two philosophical anthropologies exemplify how Kamakura philosophers generally focused on the nature of praxis as part of an analysis of human existence. In the Heian period, the pressing philosophical question seems to have been the nature of the cosmos. In the Kamakura period it shifted to the nature of the self. Shinran and Dōgen produced particularly impressive analyses of human motivation and the structure of consciousness, and their models of the self remain influential in Japanese culture up to the present. It is significant, however, that their focus was primarily on the inner self instead of the social self. The social dimension was to become a major concern in the next major period in the development of Japanese philosophy.

6 *Neo-Confucianism, the* samurai *code and Tokugawa society*

Following the Kamakura period there were more periods of intermittent warfare and internal strife. A long-lasting, nationwide peace arrived only with the establishment of the Tokugawa family's regime as *shogun*s. For nearly all of the Tokugawa period (1600–1868) Japan closed itself off from most interaction with outside world. For example, Christianity, which had been introduced by missionaries in the sixteenth century, was formally proscribed. The Tokugawa *shogun*s established a highly bureaucratic government, giving them unprecedented control over Japanese society from its system of education to its business practices and religious institutions. In this context, much of philosophy turned to the interests of the state and the definition of social responsibility.

During the fifteenth and sixteenth centuries, Japan had again received a strong infusion of foreign thought. In particular, Zen Buddhist monks who had visited the mainland brought back to Japan texts of the neo-Confucian traditions established in China by Zhu Xi and Wang Yangming. Since Japanese Buddhist philosophy taught little about social responsibility in secular contexts, the ethical

dimension of these texts attracted increasing attention. Neo-Confucianism went further than traditional Confucianism by adding a metaphysical level to explain the natural world and how it could be known.

From ancient times Confucianism had played a major role in the social, bureaucratic and ethical structures of Japanese culture. In trying to organize and stabilize the government after centuries of warfare, the Tokugawa *shogun*s were naturally intrigued by this new and more comprehensive form of the social philosophy that had already served Japan in the past. Furthermore, wary of Buddhism's popularity, they probably welcomed neo-Confucianism's challenge to the near hegemony that Buddhism had established in Japanese philosophy. In any case, from early in the seventeenth century, the Tokugawa *shogun*s gave special status and support to neo-Confucianism, especially to the school called Shushigaku, the Japanese school of Zhu Xi.

With the increased peace and prosperity of the Tokugawa period, there was a new market for philosophical education, especially in the great urban centres of Kyoto, Osaka and Edo (now Tokyo). The rising merchant class wanted the social polish of an upper class education. Furthermore, because it was peacetime, many unemployed *samurai* wanted a classical education to qualify for positions in the government bureaucracy. The result was an increase in independent schools and a proliferation of teachers with different philosophical approaches.

Generally we find major philosophical development during the Tokugawa period in two areas: naturalistic metaphysics and social philosophy or ethics. The Shushigaku school introduced a theory of reality or metaphysics foreign to the Buddhist theories so entrenched in Japanese thought. In particular, it analysed reality in terms of the dynamic between 'configuration' or 'principle' (*ri*; in Chinese, *li*) and 'material energy' or 'vital force' (*ki*; in Chinese, *qi*). According to Shushigaku, *ri* gives the universe its structure and, since *ri* is also in the mind, it is the foundation of knowledge. By 'investigating the nature of things' we come to know *ri*, both in ourselves and in the things we study. *Ki*, on the other hand, was considered the basic stuff that is ordered by *ri*.

Although the notion of *ri* was known to the Japanese through Tendai and Kegon Buddhism, the neo-Confucians gave the term a distinctive emphasis. They embedded it into the broader enterprise of understanding of the natural world. During the Tokugawa period there was a practical interest in better understanding nature; in the sixteenth century traders and missionaries from Europe had introduced some Western science. With the closure of Japan this contact was severely limited, although the occasional Dutch treatise on practical science or medicine did find its way into Japan.

For the most part, Japanese philosophers found the Shushigaku emphasis on *ri* to be overly abstract. To many, it seemed that *ri* was an unnecessary transcendent realm behind physical reality that could be known only through some mysterious half-contemplative, half-empirical study. In response, many Japanese thinkers took a more phenomenalistic approach. Kaibara Ekken (1630–1714), for example, argued for the primacy of *ki*. To him, *ki* was the basic constituent of reality and should be studied directly; *ri* was no more than the name for the patterns one could abstract from the behaviour of *ki*. Certainly from the perspectives of both medicine and the martial arts, *ki* became the more important category in Japan.

Other naturalistic philosophers such as Miura Baien (1723–89) developed intricate systems of their own for categorizing natural phenomena. Such indigenous concerns for observation and classification of the natural world may not have developed into a full-blown science in the Western sense, but the orientation did show an increasing Japanese concern for observing and understanding the natural world. This phenomenalist tendency would serve Japan well in the nineteenth century when Western science and technology were reintroduced.

In the field of social or moral philosophy, an important development was the emergence of the school of 'Ancient Learning'. Led by Yamaga Sōkō (1622–85), Itō Jinsai (1627–1705) and Ogyū Sorai (1666–1728), these philosophers rejected the metaphysical speculations of the neo-Confucianists and tried to return to the early classics of the Confucian tradition, especially the *Analects* (see Chinese philosophy; Confucian philosophy, Chinese; Confucius). They developed sophisticated philological and exegetical skills as tools for attempting to discover the original meanings of those texts. Their goal was to clarify traditional Confucian social philosophy so that it could become the basis for Japanese society. In this regard, the school of Ancient Learning put its emphasis on the nature of virtue and the development of character. Ogyū Sorai had an especially broad impact on society for his theories about education and moral training.

Some philosophers, like Yamaga Sōkō of the Ancient Learning School, mixed Confucian values with warrior values about loyalty and honour. Yamaga tried to develop a warrior mentality for service to the state that would be appropriate to peacetime. Furthermore, in their unemployment, many *samurai* entered the various Buddhist orders, especially Zen, where they found a familiar

emphasis on discipline and regimentation. The combined result was an idealized code of the warrior (*bushidō*) as a way of life, even for non-*samurai* and even in times of peace.

7 Native studies: religio-aesthetic foundation of the Shintō state

The school of Ancient Learning's return to the original classics of Chinese Confucianism was mirrored in a movement to return to the early texts of Japan, the school of 'Native Studies' or 'National Studies' (*kokugaku*). Originally a literary and philological group, Native Studies scholars like Keichū (1640–1701), Kada no Azumamaro (1669–1736) and Kamo no Mabuchi (1697–1769) analysed the language and worldview of Nara and Heian poetry and prose. The school expanded beyond these literary goals, however, as it turned to questions of religion and national identity. In this development the philosophy of Motoori Norinaga (1730–1801) played a pivotal role.

The major shift in Native Studies began with Motoori's decision as a philologist to decode the antiquated writing system of the *Kojiki* (The Record of Ancient Matters). An eighth-century text, the *Kojiki* was supposedly the written version of what had formerly been an oral tradition. Mixing myth and history, it discussed the origins of the world, the formation of Japan and the succession of Japanese emperors from the beginning of time up to its present. There was a twin work in Chinese written at the same time, *Nihon shoki* (The Chronicle of Japan). Because the orthography of the *Kojiki* died out as a writing system for Japanese shortly after the Nara period, the *Nihon shoki* became the more used text, supposedly containing the same information. The *Kojiki* had in fact become virtually unintelligible even to the educated Japanese of Motoori's time. By decoding the text, therefore, Motoori hoped to bring to light the original Japanese worldview.

A devout follower of Shintō, Motoori's task assumed a profoundly religious dimension as well. He believed the *Kojiki* was a written account of what had been orally transmitted word for word from the time of creation. The *Kojiki* contained the very words of the deities who had created the world. Furthermore, since the text was written in an orthography that had soon fallen into disuse, Motoori believed the written text was uncorrupted by later interpreters, making it superior to the adulterated cosmogonies of other cultures. This firm belief sustained Motoori's lifelong devotion to the enormously complex task of decoding the text.

Based on his readings of Japanese classics, Motoori also developed a philosophy of poetic or religious expression: his theory of 'heart' (*kokoro*). As a technical term, *kokoro* designates the seat of thinking and feeling; it is the basis of sensitivity. Heart is not, however, limited to people; things and words also have heart. If poets have 'genuine heart,' they will be touched by the heart of things and the heart of words. The poetically or religiously expressive act, therefore, is an act of the heart, something shared by the things, the person and the words. Since the genuine heart is also a goal of Shintō purification, Motoori saw in this theory the basis of religious language as well. This in turn influenced his understanding of the significance of the *Kojiki*.

If the *Kojiki* represents the original words of the deities at the time of creation, to read or study the text is virtually a ritualistic re-enactment of creation. The implication for Motoori was that the ancient Japanese language of the text is not only the language of the deities, but also the most pure intimation of the heart of things. By this line of reasoning, Motoori made the *Kojiki* into the sacred scripture of Shintō. Based on his reading of the text, Motoori founded a philosophy of Shintō supposedly free of Buddhist influence. For virtually the first time, Shintō could develop a formal doctrinal system of its own (see SHINTŌ).

This line of thought readily supported a nationalist ideology. If the ancient Japanese language was the protolanguage of all languages, if that language were most purely resonant with the heart of things and if the Japanese emperor was the special link between the deities and humanity, obviously Japan would have a special place in the world. This sense of national superiority became especially strong in the next generation of Native Studies scholars such as Hirata Atsutane (1776–1843) and helped contribute to the movement to overthrow the Tokugawa shogunate and restore the emperor as the true leader of Japan. In this effort, it found an intellectual ally in the Mito School, a Shintō–Confucian synthesis, that argued for the centrality of the emperor as the 'body of the state'. The restoration of the emperor was completed in 1868, the beginning of Japan's modern era.

In summary, the introduction of neo-Confucianism from China and the establishment of a stable state under Tokugawa rule created a new fertile environment for Japanese philosophy. Ultimately, neo-Confucianism itself did not become a dominant philosophy in Japan, but its presence challenged the dominant Buddhist philosophies. In this new context Japanese philosophy grew more concerned with social ethics, the study of the natural world and cultural identity. In this period developed the idea of the warrior-turned-bureaucrat, as fiercely loyal to the organization as formerly

to the lord. As there was more interest in studying and classifying the physical processes of nature, there was also a newly defined aesthetic of sensitivity and poetic expression. For the first time, Shintō became a major intellectual force in Japanese thought and there was an attendant sense of the uniqueness and superior quality of Japanese culture. All these factors became the intellectual background for the emergence of the modern era after 1868, and its related philosophies.

8 Modern Japanese philosophy and its critique of Western philosophy

The Tokugawa policy of seclusion ended with the appearance of US gunboats in 1854 and their demand that Japan open itself to international trade. To protect its sovereignty from infringement by the Western powers, Japan believed it had to become a modern industrial and military power in its own right. The government sent its brightest young intellectuals to Europe and the United States to study what was needed for modernization, such as medicine, engineering, agriculture, postal systems and education. This effort included the study of Western thought as a means to understanding Western society and the ideas behind its science and technology. Although there was some sustained interest in American pragmatism (see PRAGMATISM), most Japanese philosophers turned toward Germany for their inspiration (see GERMAN IDEALISM).

Throughout the nineteenth century, most Japanese leaders hoped Japan could superimpose Western science and technology on a society that remained true to Asian cultural values. By the first decade of the twentieth century, Japan had successfully developed the technology and military might needed to defeat both Russia and China in wars. Many Japanese intellectuals feared, however, that this was at the expense of traditional values. The ideal of detached objectivity in Western science threatened the tradition of apprenticed learning through imitation of the master. The Buddhist and Confucian theories of reality were in jeopardy of being overwhelmed by Western scientism. The new egalitarian ideals of education so helpful in developing a technological society were also part of a democratic worldview that emphasized the individual as basic unit of society and threatened the traditional Confucian virtues and social hierarchy. How to negotiate the differences between traditional Asian and modern Western values became a major concern among Japanese philosophers in the first half of the twentieth century.

The most influential development in modern Japanese philosophy was the emergence of the Kyoto School of thought. By the early twentieth century, philosophy had become an academic study in Japanese universities. An influential circle of philosophers clustered around NISHIDA KITARŌ (1870–1945), a professor at Kyoto University. This group tended to address problems about the meaning of self, the nature of knowledge, the role of spirituality and the place of both ethical and aesthetic value.

Nishida was the single most influential philosopher of the prewar period. His philosophical goal was to locate empiricism and scientific thinking within a larger system that would also give value judgements a non-subordinate place. *Zen no kenkyū* (An Inquiry into the Good), his first major work, developed the notion of 'pure experience', an idea adapted from William JAMES and perhaps developed in light of Nishida's own Zen Buddhist practice. The book's theme is that there is a thrust toward unity in all experience. Thought arises out of the disruption of the unity of immediacy and serves as a means to establishing a more comprehensive unity. In Nishida's phrase, pure experience is the 'alpha and omega of thought'.

Nishida himself subsequently decided this early effort was too 'psychologistic' and 'mystical', and developed a different philosophical system in the 1920s and 1930s that emphasized the 'logic of place (or *topos*)'. According to Nishida, every judgment is restricted by the logic of its context, which in turn derives from a broader experiential domain that it cannot explain in its own terms. An empirical judgment, for example, excludes the subject of the experience (see EMPIRICISM). Its internal logic precludes the consideration of the self. Yet, of course, there can be no empirical data without an experiencing subject; so, the logical place within which empirical judgments are made is within a broader experiential context that assumes the function of the self. If that broader context is then made the logical domain for judgments, we have idealism. In turn, according to Nishida, the experiential locus that makes idealist judgments possible cannot be spoken of logically within the domain of idealism. Nishida calls this experiential locus 'place of absolute nothingness', the ground of 'acting-intuiting'. This region cannot be expressed in any logical form, but is the basis of all logical expression. It is also the ground of value: spiritual, ethical and aesthetic.

In this way, Nishida argued that the realm of empirical judgment is necessarily grounded experientially in a realm of value that it cannot analyse from its own standpoint. Nishida's system attempted to grant Western science its logical place while showing that its experiential ground was what traditional Asian values had affirmed all along.

Religion, at least in its Asian forms, was not antagonistic to science, nor was it endangered by science. On the contrary, Nishida argued that spiritual experience is what makes science logically possible.

Nishida argued for the synthesis of Eastern values and Western values by analysing the logic of epistemology. He was joined in this logical or epistemological approach by other philosophers connected in some way with the Kyoto School such as TANABE HAJIME (1885–1962) and Nishitani Keiji (1900–90). Other Kyoto School philosophers addressed the issue from the other direction, by analysing values. Hisamatsu Shin'ichi (1889–1980), for example, analysed the religio-aesthetic worldview of Zen Buddhism, advocating it as the basis for a style of life. Miki Kiyoshi (1897–1945), on the other hand, developed a 'logic of creativity' inspired by both Buddhist and Marxist theories of praxis.

Among the modern Japanese ethicists, the most influential was Watsuji Tetsurō (1889–1960), a professor at Tokyo University and not technically a member of the Kyoto School. Watsuji explained that Western ethics takes the individual for its prime locus. Western ethics is constituted *vis-à-vis* individual needs and the focus of morality is the individual agent. In contrast, Watsuji said, Confucian ethics takes the social as its prime locus, being constituted out of the primary social relations. Watsuji maintained both traditions are faulty in seeing only one dimension of the whole. As an alternative, he developed a philosophical anthropology emphasising 'betweenness', a dialectical tension between the individual and the collective. The collective establishes norms within which one can act in a given society, whereas the individual serves as the locus of freedom. If unqualified by the opposing pole, the collective suppresses freedom and the individual rejects the objective validity of norms.

Watsuji concluded, therefore, that true ethical behaviour is possible only as a 'double negation' that rejects both poles without settling in either. In this 'betweenness' we find the dialectical tension between the social and the individual, the fundamental definition of our human being. So, the nature of ethics follows from the definition of human being, and ethics is the fundamental way of realizing our humanity. Watsuji developed these ideas first in his *Ningen no gaku to shite no rinrigaku* (Ethics as the Study of Human Being) (1934) and then more fully in his *magnum opus*, a three-volume work called simply *Rinrigaku* (Ethics) (1937–49).

9 Postwar developments

The defeat in the Second World War caused many philosophers to rethink their positions. Tanabe and Watsuji, for example, explicitly repented some of the nationalistic implications of their earlier writings. In his *Zangedō to shite no tetsugaku* (Philosophy as Metanoia) in 1946, Tanabe developed an intricate, self-critical dialectical method to check the emergence of philosophical ideologies. In conceiving this method he drew inspiration from the philosophical analysis of Shinran's thought done by one of his students, Takeuchi Yoshinori. The connection with religious philosophy has become a recurrent theme in the further development of the Kyoto school as exemplified in the works of Nishitani, Takeuchi and Ueda Shizuteru. In a spirit reminiscent of the Kamakura Buddhist thinkers, many of the postwar philosophers have turned inward to re-examine the nature of human existence, now able to be formulated in relation to the problematics of existentialism as well as Buddhism.

At the same time some Japanese philosophers have continued to specialize in the scholarly study of Western philosophy. In many Japanese universities there are departments of philosophy where much of the work is indistinguishable from what might find in a philosophy department in Europe or North America. In general, the Continental traditions of philosophy, rather than the British analytic traditions, continue to dominate.

Lastly, and especially since the 1960s, there are individuals and groups of philosophers who have explored new provocative directions, drawing their ideas from a wide variety of sources including Western science, psychoanalysis and phenomenology as well as traditional Asian thought and medicine. This phenomenon is another example of a recurrent pattern in the history of Japanese philosophy: the assimilation and adaptation of foreign ideas against the background of an ongoing tradition.

(Not an integrated book but a set of seven excellent essays on different periods of Japanese philosophy. Now out-of-print, but still one of the most insightful discussions in English.)

Tsunoda, R., de Bary, W.T. and Keene, D. (eds) (1964) *Sources of Japanese Traditions*, New York: Columbia University Press, 2 vols. (Extensive collection of short excepts from philosophical texts in translation, including brief but useful introductions to each writer.)

THOMAS P. KASULIS

JASPERS, KARL (1883–1969)

Karl Jaspers is generally known as an existentialist, but he also developed interesting conceptions in other fields of philosophy: in philosophy of religion, the concepts of Transcendence, cipher and philosophical faith; in philosophy of history, the thesis of an Axial Period in history; in political philosophy, the idea of a new, reasonable politics. His existentialism deals mainly with personal moral attitudes and private aspects of individual self-realization in boundary situations and intimate interpersonal communication. His political philosophy concentrates on controversial political affairs and some of the urgent problems of his age (for example, the possibility of extinguishing all life on earth by the atom bomb, or of establishing a world-wide totalitarian regime).

JEWISH PHILOSOPHY

Introduction

Jewish philosophy is philosophical inquiry informed by the texts, traditions and experiences of the Jewish people. Its concerns range from the farthest reaches of cosmological speculation to the most intimate theatres of ethical choice and the most exigent fora of political debate. What distinguishes it as Jewish is the confidence of its practitioners that the literary catena of Jewish tradition contains insights and articulates values of lasting philosophical import. One mark of the enduring import of these ideas and values is their articulation in a variety of idioms, from the mythic and archetypal discourse of the Book of Genesis to the ethical and legislative prescriptions of the Pentateuch at large, to the admonitions of the Prophets, the juridical and allegorical midrash and dialectics of the Rabbis, and to the systematic demonstrations, flights of imagination, existential declarations and apercus of philosophers in the modern or the medieval mode.

1 The nature of Jewish philosophy

Students of Jewish philosophy, especially those who aspire to contribute a window or a wing to the edifice, must learn many languages, to read and listen to voices very different from their own. Just as the writers of the Genesis narratives or of the Pentateuch had to recast and reinvent the ancient creation myths and the ancient Babylonian laws to express the distinctively universal ethical demands and aesthetic standards of their God, and just as the Deuteronomist had to rediscover the ethical core in the original Mosaic legislation, hearing God's commands now as urgent reminders through the very human voice of Moses, so in every generation new interpreters are needed, to rediscover what is essential and living in the tradition. Such interpreters have always needed to negotiate the rapids of historical change – not just with regard to idiom but also with regard to content, refocusing and restructuring the living tradition, sculpting it philosophically with their own moieties of reason. Such thinkers have worked always with a view to the continuity of the tradition; that is, to the faithfulness of its future to its past, but also to the vitality and vivacity of what they found timeless in the tradition and therefore capable of acquiring new meanings and new spheres of application in the present.

The confidence of the practitioners of Jewish philosophy in the conceptual vitality and continually renewed moral and spiritual relevance of the tradition is typically the reflex of an existential commitment to that tradition and to the people who are its bearers. That confidence, and its repeated vindication by the richness of the tradition itself, is also a wellspring of renewal and encouragement for the commitment that energizes it – even, and especially, in times of historical crisis and external pressures, which have rarely confined themselves to purely intellectual challenges. Symptomatic of that commitment is the prominence and recurrence of the philosophy of Judaism among the concerns of Jewish philosophy. However, the two should not be confused. The philosophy of Judaism is inquiry into the nature and meaning of Jewish existence. Its questions address the sense to be given to the idea of a covenant between the universal God and the people of Israel, the meaning of that people's mission, their chosenness, their distinctive laws, customs and rituals and the relation of those norms to the more widely recognized norms of humanity, of which the Prophets of Israel were early and insistent messengers.

The philosophy of Judaism wants to understand Zionism, the Holocaust, the Jewish Diaspora and the historical vicissitudes that gave shape to Jewish

experience over the millennia, from the age of the biblical patriarchs to the destruction of the first and second temples in Jerusalem, to the exile of the Jewish people and the return of many, after a hundred generations, to the land they had been promised and in which they had prospered, a land which some had never left but which most, for centuries, had pictured only through the sublimating lenses of sacred history, apocalypse and philosophy. The philosophy of Judaism wants to understand the ancient Jewish liturgy, the exegetical practices and hermeneutical standards of the Jewish exegetes. Like Freud, it wants to understand Jewish humour. Like Pico della Mirandola, it wants to understand Kabbalah, Jewish mysticism, and like Buber, it wants to understand Hasidism. The concerns of the philosophy of Judaism touch every aspect of Jewish experience, just as the concerns of philosophy at large touch every aspect of experience in general. But the concerns of Jewish philosophy, like those of general philosophy, do not confine themselves to Jewish experience. They are, in fact, the same concerns as those of general philosophy, rendered distinctively Jewish by their steady recourse to the resources of the tradition, and sustained as philosophical by an insistence on critical receptivity, responsible but creative appropriation of ideas and values that withstand the scrutiny of reason and indeed grow and give fruit in its light.

2 Strengths and weaknesses

There are two weaknesses in Jewish philosophy as practised today. One is a tendency to historicism, that is, the equivocal equation of norm with facticity and facticity with norm that leads to an abdication of philosophical engagement for a detached clinical posture or an equally unwholesome surrender of judgment to the flow of events. Historicism is a natural by-product of respect for tradition, or of expectation of progress. It becomes particularly debilitating under the pressure of positivism, whether of the logical empiricist sort that dominated philosophy for much of the early twentieth century, or of the more endemic sort that thrives on the sheer givenness of any system of law and ritual or that allows itself to be overwhelmed by the press of history itself. It is not unusual, even today, when logical positivism is widely thought to be long dead, to find scholars of Jewish thought who substitute historical descriptions for philosophical investigations, often in the process begging or slighting the key philosophical questions. Nor is it unusual among those of more traditional stamp for scholars to be found who imagine that a faithful description of the contents of authentic Jewish documents constitutes doing Jewish philosophy – as though faithfulness to the tradition were somehow a substitute for critical grappling with the issues and problems, and as though the question as to what constitutes faithfulness to the tradition, conceptually, historically, morally and spiritually, were not itself among the most crucial of those issues and problems.

The second weakness is a narrowing of the gaze, a tendency to substitute philosophy of Judaism for the wider discourse of Jewish philosophy, as though the resources of the tradition had nothing (or nothing more) to contribute to ethics, or natural theology, or metaphysics and logic, for that matter. The work of the great practitioners of Jewish philosophy has repeatedly given the lie to such narrow expectations. In every epoch of its existence, Jewish philosophy has played an active role in the philosophical conversation of humankind – which is a universal conversation precisely because and to the extent that those who take part speak every language and bring to the conversation experiences that are universal as well as those that are unique.

But if two weaknesses are to be mentioned here, at least one strength should be cited as well: Jewish philosophy, although intimately engaged throughout its history with the philosophical traditions of the West, has also been a tradition apart. The open access of most of its practitioners to the Hebrew (and Aramaic) Jewish sources has afforded a perspective that is distinctive and that can be corrective of biases found in other branchings of the tree of philosophical learning. The early access of medieval Jewish philosophers to Arabic philosophical and scientific writings, and to the Greek works preserved in Arabic, enriched and broadened their philosophical repertoire. The scholastic learning of later medieval Jewish philosophers and their collaboration with scholastic thinkers made them at once participants in and observers of the lively philosophical debates of their day. The immersion and active participation of Renaissance and Enlightenment Jewish philosophers in the movements that spawned modernity gave them a similar philosophical vantage point. All philosophers must be, to some degree, alien to their society – Socrates and Nietzsche, and for that matter even Plato, Aristotle and Descartes were, to some degree, intellectual outsiders in their own times – not so alien as to have no word or thought in common with their contemporaries, but not so well integrated as to become mere apologists, or complacent and unquestioning acquiescers in the given. Jewish philosophy has long made and continues to make a distinctive, if today underutilized, contribution to cosmopolitan philosophical discourse in this regard. It shares the problematic of Western philosophy but typically offers a distinctive slant or perspective that calls into

question accepted verities and thus enhances the critical edge of philosophical work for those who study it.

3 Movements and important figures

Jewish philosophy has over the course of its history been the source of a number of different types of study based on the philosophically relevant ideas of the Hebrew Bible, Rabbinic Law (Halakhah), Rabbinic theology and Rabbinic homiletics, exegesis and hermeneutics (midrash) (see HALAKHAH; MIDRASH). The anti-Rabbinical, biblicist movement known as Karaism and the mystical tradition of the Kabbalah are examples of differing types of movements which have emerged (see KABBALAH), while Jewish voluntarism and Jewish Averroism were fields for the rivalry between intellectualist and less deterministic, more empiricist views of theology as it was played out among Jewish thinkers. More modern movements include the Jewish pietist movement founded by Israel Baal Shem Tov and known as Hasidism, the Jewish Enlightenment movement known as the Haskalah, and Zionism, the movement that led to the establishment of the modern State of Israel (see HASIDISM).

The first exponent of Jewish philosophy was PHILO OF ALEXANDRIA, a major contributor to the synthesis of Stoicism, Middle Platonism and monotheistic ideas that helped forge the tradition of scriptural philosophy in the West. Other early figures include Daud al-Muqammas and Isaac Israeli, two of the first figures of medieval Jewish philosophical theology. Al-Fayyumi Saadiah Gaon (882–942), the first systematic Jewish philosopher, was also a major biblical translator and exegete, a grammarian, lexicographer and authority on Jewish religious law and ritual. The rationalism, pluralism and intellectual honesty evident in his work made it a model of Jewish philosophy for all who came after him. Solomon ibn Gabirol (*c.*1020–*c.*1057), long known as a Hebrew poet, was discovered in the nineteenth century to have been the author as well of the famous Neoplatonic philosophical work, preserved in Latin as the *Fons Vitae*. Moses ibn Ezra (*c.*1055–after 1135) is notable for his poetic and philosophic conributions. Abraham ibn Ezra (*c.*1089–1164) is likewise noted for his hermeneutical ideas and methods; his forthright approach to the Hebrew Bible was a critical influence on the thinking of Jewish philosophers from the Middle Ages to SPINOZA and beyond. A less familiar figure is Abu 'l-Barakat al-Baghdadi (*fl. c.*1200–50), a brilliant Jewish thinker who converted to Islam late in life. He developed highly independent views about the nature of time, human consciousness, space, matter and motion. His work undercuts the notion that the medieval period was simply an age of faith and static commitment to a faith community.

A polymath of rather different spirit was Abraham bar Hayya in the eleventh century, who wrote on astronomy, mathematics, geography, optics and music as well as philosophy and who collaborated on scientific translations with the Christian scholar Plato of Tivoli, the transmitter of the Ptolemaic system to the Latin world. Bar Hayya's *Meditation of the Sad Soul* expresses the forlornness of human life in exile from the world of the divine, a forlornness tinged with the hope of future glory. Joseph ibn Tzaddik (d. 1149) similarly developed Neoplatonic ideas around the theme of the human being as a microcosm.

Bahya ibn Pakuda (early twelfth century) wrote as a pietist philosopher. He placed philosophical understanding and critical thinking at the core of the spiritual devotion called for by the sincerest form of piety. Judah Halevi (before 1075–1141), probably the greatest Hebrew poet after the Psalms, wrote a cogently argued philosophical dialogue best known as the *Kuzari*, but more formally titled, *A Defence and an Argument in behalf of the Abased Religion*. Set in the Khazar kingdom, whose king, historically, had converted to Judaism, the work mounts a trenchant critique of the intellectualism of the prevalent philosophical school and the spiritualizing and universalizing ascetic pietism that was its counterpart. Calling for a robust recovery of Jewish life and peoplehood in the Land of Israel, the work is not only a striking anticipation of Zionist ideas but a remarkable expression of the need to reintegrate the spiritual, intellectual, moral and physical dimensions of Jewish life.

Abraham ibn Daud (*c.*1110–80), a historian as well as a philosopher, used his historiography to argue for the providential continuity of the Jewish intellectual and religious tradition. His philosophical work laid the technical foundations that made possible the philosophical achievement of Moses MAIMONIDES (1138–1204), the greatest of the philosophers committed to the Jewish tradition. Besides his medical writings and his extensive juridical corpus, which includes the authoritative fourteen-volume code of Jewish law, the *Mishneh Torah*, Maimonides was the author of the famous *Guide to the Perplexed*. Written in Arabic and intended for an inquirer puzzled by the apparent discrepancies between traditional Judaism and Aristotelian-Neoplatonic philosophy, the *Guide* is a paradigm in the theology of transcendence, addressing questions ranging from the overt anthropomorphism of the scriptural text to the purposes of the Mosaic legislation, to the controversy over the creation or eternity of the world, the problem of evil, and the sense that can be made of the ideas

of revelation, providence, divine knowledge and human perfectibility. Like Halevi's *Kuzari* and Bahya's *Duties of the Heart*, the *Guide to the Perplexed* continues to be studied to this day by Jews and non-Jews for its philosophical insights.

Abraham ben Moses Maimonides (1186–1237), the son of the great philosopher and jurist, began his scholarly life as a defender of his father's work against the many critics who feared Maimonidean rationalism. In his mature work he became the exponent of a mystical, pietist and ascetic movement, largely influenced by Sufism. Moses Nahmanides (1194–1270), exegete, theologian and a founding figure of the Kabbalistic theosophy, championed Judaism in the infamous Barcelona Disputation of 1263 and played a leading role in the Maimonidean controversy. He struggled to harmonize his conservative and reactive tendencies with his respect for reason and the unvarnished sense of the biblical text.

Ibn Kammuna (d. 1284) was a pioneer in other areas. Besides his work in the Ishraqi or Illuminationist tradition of theosophy, laid out in commentary on the Muslim philosopher Ibn Sina (Avicenna), he wrote a distinctively dispassionate study of comparative religions, favouring Judaism but fairly and unpolemically presenting the Christian and Muslim alternatives.

Shem Tov ibn Falaquera (*c.*1225–*c.*1295) was a warm exponent of Maimonidean rationalism and an ardent believer in the interdependence of faith and reason. His selections in Hebrew from the lost Arabic original of Ibn Gabirol's magnum opus allowed modern scholars to identify Ibn Gabirol as the Avicebrol of the surviving Latin text, the *Fons Vitae*.

Hillel ben Samuel of Verona (*c.*1220–95), physician, translator, Talmudist and philosopher was a Maimonist who introduced numerous scholastic ideas into Hebrew philosophical discourse. Immanuel of Rome (*c.*1261–before 1336) was a prolific author of philosophical poetry and exegesis, often praising reason and intellectual love. Judah ben Moses of Rome (*c.*1292–after 1330), known as Judah Romano, was an active bridge person between the Judaeo-Arabic and the scholastic tradition of philosophical theology.

Levi ben Gershom, known as Gersonides (1288–1344), was an important astronomer and mathematician as well as a biblical exegete and philosopher. His *Wars of the Lord* grappled with the problems of creation, providence, divine knowledge, human freedom and immortality. Aiming to defend his ancestral faith, Gersonides followed courageously where the argument led, often into radical and creative departures from traditional views.

Hasdai Crescas (1340–1410), an ardent defender of Judaism against Christian conversionary pressures, was among the most creative figures of Jewish philosophy, challenging many of the givens of Aristotelianism, including the idea that the cosmos must be finite in extent. Crescas' student Joseph Albo (*c.*1360–1444) sought to organize Jewish theology into an axiomatic system, in part to render Jewish thought defensible against hostile critics.

Profiat Duran (d. *c.* 1414), also known as Efodi, used his extensive understanding of Christian culture to criticize Christianity from a Jewish perspective. Deeply influenced by Moses Maimonides and Abraham ibn Ezra and by Neoplatonic and astrological ideas, he sought to balance the practical with the intellectual aspects of the Torah. Simeon ben Tzemach Duran (1361–1444) contributed an original approach to the project of Jewish dogmatics and an implicit critical examination of that project.

The Shem Tov family included four thinkers active in fifteenth-century Spain. Their works follow the persecution of 1391 and the ensuing mass apostasy of Spanish Jews and seek to rethink the relations of philosophy to Judaism. Shem Tov, the *paterfamilias*, criticized Maimonides and endorsed Kabbalah, but his sons Joseph, a court physician and auditor of royal accounts at Castile, and Isaac, a popular teacher of Aristotelian philosophy, and Joseph's son, again named Shem Tov, wrote numerous Peripatetic commentaries. These offspring charted a more moderate course that enabled Jewish intellectuals to cultivate philosophy and the kindred arts and sciences while asserting the ultimate primacy of their revealed faith.

Isaac ben Moses Arama (*c.*1420–94), like Nahmanides, was critical of Maimonidean and Aristotelian rationalism but did not discard reason, seeing in it a crucial exegetical tool and an avenue toward understanding miracles and providence. Isaac Abravanel (1437–1508), leader of the Jews whom Ferdinand and Isabella exiled from Spain in 1492, like Arama criticized Maimonidean rationalism in the interest of traditional Judaism as he saw it, but at the same time put forward a theistic vision of history and strikingly modern views about politics and the state. His son, Judah ben Isaac Abravanel, also known as Leone Ebreo (*c.*1460–*c.*1521), wrote the *Dialoghi d'amore*. Couched in the language of courtly love, the work explores the idea that love is the animating force of the cosmos. The work stands out as a brilliant dialectical exploration of the differences and complementarities of the Platonic and Aristotelian approaches to philosophy.

Judah Messer Leon (*c.*1425–*c.*1495) was a philosopher, physician, jurist, communal leader, poet and orator. Awarded a doctorate in medicine and philosophy by the Emperor Frederick III, he

could confer doctoral degrees in those subjects on the students in his *yeshivah*. He saw logic as the key to harmonizing religion and philosophy and favored scholastic logic over the Arabic logical works. His encyclopedia became a popular textbook, and his systematic elicitation of Hebrew rhetoric from the biblical text, in *The Book of the Honeycomb's Flow*, one of the first Hebrew books to be printed, was a masterpiece of cross-cultural humanistic scholarship. But Messer Leon failed to curb the spread of Kabbalah, whose underlying Platonic metaphysics he abhorred and whose appropriation by Christian Platonists he held in deep suspicion. Indeed, his own son turned toward the Kabbalah and sought to combine its teachings with the Aristotelianism favored by his father.

Yohanan ben Isaac Alemanno (1433/4–after 1503/4) brought together in his thinking Averroist, Kabbalistic, Neoplatonic and Renaissance humanist themes. He instructed Pico della Mirandola in Hebrew and in Kabbalah, bringing to birth what became a Christian, syncretic Kabbalism. Elijah Delmedigo (*c*.1460–93) was an Aristotelian and Averroist. He translated works into Latin for Pico della Mirandola and developed a subtle critique of the Kabbalistic ideas that in his time were rivalled and often displaced what he saw as more disciplined philosophical thinking. Abraham Cohen de Herrera (*c*.1562–*c*.1635) was a philosophically oriented Kabbalist of Spanish origin. His Spanish writings, in Latin translation, were blamed for inspiring Spinoza's views.

4 Movements and important figures (cont.)

Moses Mendelssohn (1729–86), a leading figure of the European Enlightenment, spread Enlightenment ideas to Hebrew literature, fought for Jewish civil rights and did pioneering conceptual work on political theory, especially with regard to religious liberty in his Jerusalem. Solomon Maimon (1753/4–1800) took his name in honour of Moses Maimonides. Trained as a rabbi, he pursued secular and scientific learning and became an important and original critic of the philosophy of Kant. Nachman Krochmal (1785–1840), a leader of the Jewish Enlightenment in Galicia, found anticipations of Kant, Hegel and Schelling in the ancient Jewish writings. His work shows how a thinker whose underlying assumptions differ from those of the idealist philosophers could take their views in quite a different direction from the one they chose.

Hermann Cohen (1842–1918), a major Kantian philosopher and one of the first non-baptized Jews to hold an important academic post in Germany, applied his own distinctive version of critical idealism to the understanding of Judaism as a spiritual and ethical system. Franz Rosenzweig (1886–1929), an important Hegelian thinker, went on to formulate a Jewish existential philosophy that deeply influenced many of the most prominent Jewish thinkers of the twentieth century. Martin Buber (1878–1965), Zionist advocate of accommodation with the Palestinian Arabs and an admiring student of Hasidic traditions, added his own stamp to the Continental tradition of Jewish philosophy by developing a widely influential dialogical philosophy that privileged relationships experientially and celebrated the I–thou, a mode of relation that allows for authentic encounter.

A number of twentieth-century philosophers of Judaism have grasped at diverse threads of the Jewish experience, illustrating both the attractions of the tradition and the fragmentation produced by centuries of persecution that would culminate in the Holocaust, only to be accentuated by the centrifugal tendencies of Jewish life in post-Holocaust liberal societies. Ahad Ha'Am, the pen name of Asher Ginzberg (1856–1927), was an essayist who argued that the creation of a 'spiritual centre' of Jewish culture in Palestine would provide the sustenance needed to preserve the diaspora Jewry from the threat of assimilation. No state was needed. David Baumgardt (1890–1963) was a philosopher who sought to reconcile ethical naturalism with the ideals he found in the Jewish sources, but, unlike Hermann Cohen, Baumgardt did not explore those sources in close detail. Mordecai Kaplan (1881–1981) sought to devise a social mission and communal identity for Jews without reliance on many of the core beliefs and practices that had shaped that identity in the past. Abraham Joshua Heschel (1907–72) sought to salvage the spiritual dimensions of Jewish experience, which found expression both in ritual and in ethical and social action. Joseph Soloveitchik (1903–93) gave canonical expression to Orthodox ideals by focusing on the intellectual and ritual rigours of his archetypal figures, Halakhic man and the Lonely Man of Faith. Yeshayahu Leibowitz (1903–94), an influential Israeli thinker, struggled for the disengagement of authentic and committed religious observance from the toils of governmental officialdom. Jews are mandated, he argued, to observance, as a community. That imperative is not to be put aside. Neither can the observant pretend to ignore the State of Israel. But the State can give no mandate to religious observance, and religious faithfulness can impart none of its aura to the State. For it is essential not to place God in the service of politics. Emil Fackenheim (1916–) seeks an authentic response to the Holocaust, which he formulates in an intentionally inclusionary way, as a

'614th' commandment, not to hand Hitler a posthumous victory but to find some way, that might vary from individual to individual, of keeping alive Jewish ideas, practices and commitments.

JOHN OF ST THOMAS (1589–1644)

The seventeenth-century Portuguese Dominican, John of St Thomas or John Poinsot, was a major figure in late scholastic philosophy and theology. Educated at Coimbra and Louvain, he taught both disciplines in Spain: at Madrid, Plasencia and Alcalá. Aspiring to be a faithful disciple of Thomas Aquinas, he published a three-volume *Cursus philosophicus thomisticus* (Thomistic Philosophical Course) and before he died began the publication of a *Cursus theologicus* (Theological Course). His philosophical writing was explicitly on logic and natural philosophy. However, in both his philosophical and theological works, he treated many metaphysical, epistemological and ethical issues. His logic is divided into two parts, formal and material. Of particular interest is his semiotic doctrine which appears in the second part. In natural philosophy, he explained Aristotle with a Thomistic slant. While following Aquinas in theology, John at times developed his master's doctrine along new lines. Both in his own time and after he has had considerable authority within scholasticism, especially for Thomists. Among those whom he has influenced in twentieth-century Thomism are Joseph Gredt, Reginald Garrigou-Lagrange, Santiago Ramirez, Jacques Maritain and Yves Simon.

JOHNSON, SAMUEL (1696–1772)

Johnson was the first important philosopher in colonial America and author of the first philosophy textbook published there. He derived his views largely from others, combining in one system elements from diverse sources. He followed the empiricists in holding that knowledge begins with sensations but held the Augustinian view that knowledge of necessary truths comes only from the mind's illumination by divine light. With Berkeley, he denied matter's existence, viewing bodies as collections of ideas. He held that these ideas are 'faint copies' of God's archetypal ideas, which he thought of in much the same way as had Malebranche and John Norris. His ethical views, influenced by William Wollaston, take happiness to be the supreme good, stressing that human beings should seek a happiness consonant with their nature as rational, immortal and social beings.

JOURNALISM, ETHICS OF

It is sometimes suggested that ethical principles, even fundamental ones like nonmaleficence and beneficence, are totally out of place in journalism, and that it should be shaped solely by market forces. This suggestion should be resisted. One reason why journalism should be ethical is that in a democracy it is expected to serve the public interest, which means that it should accept the responsibility to circulate the information and opinion without which a democracy could not operate, and to enable it to do this the freedom of the press is acknowledged.

If journalism is to serve the public interest, then a commitment to truth-telling is fundamental. Journalists should also be fair and accurate in reporting news, should publish corrections, should offer a right of reply. They should avoid discrimination, deception, harassment, betraying confidences and invasions of privacy. But ethical journalism is more than lists of requirements and prohibitions. In investigative journalism, for example, some deception or intrusion into privacy could be justified in order to uncover corruption. Ethical journalism is therefore reflective understanding of the underlying

principles of harm and benefit and the public interest, and an ability to apply them in particular cases.

JUNG, CARL GUSTAV (1875–1961)
Jung was among the leaders in the development of depth psychology at the beginning of the twentieth century. An early follower of Sigmund Freud, he broke with the founder of psychoanalysis in 1913 and established his own school of analytical psychology.

Jung's theoretical development originated in his work on the word association test and the theory of feeling toned complexes. As he continued to explore the workings of the unconscious, he postulated the existence of instinctual patterns of cognition and behaviour which he termed 'archetypes'. Archetypal patterns are, according to Jung, common throughout the human species and constitute an inherited 'collective unconscious'.

Jung's approach to psychology was eclectic. He accepted the psychological importance of any phenomenon, even if it conflicted with current thinking in other fields. This attitude led to a deep investigation of the psychological significance of occult phenomena and alchemy, which Jung viewed as expressions of the unconscious that anticipated modern psychology. Later in life, Jung turned increasingly to considerations of the contemporary cultural expressions of psychological forces, writing extensively on what he viewed to be a deepening spiritual crisis in Western civilization.

GEORGE B. HOGENSON

JUSTICE

Introduction
The idea of justice lies at the heart of moral and political philosophy. It is a necessary virtue of individuals in their interactions with others, and the principal virtue of social institutions, although not the only one. Just as an individual can display qualities such as integrity, charity and loyalty, so a society can also be more or less economically prosperous, artistically cultivated, and so on. Traditionally defined by the Latin tag '*suum cuique tribuere*' – to allocate to each his own – justice has always been closely connected to the ideas of desert and equality. Rewards and punishments are justly distributed if they go to those who deserve them. But in the absence of different desert claims, justice demands equal treatment.

One division of justice concerns compensation for the infliction of damage and as punishment for the commission of crimes. The other concerns the content of just principles for the distribution of benefits and (non-punitive) burdens. Conventionalists claim that what is due to each person is given by the laws, customs and shared understandings of the community of which the person is a member. Teleologists believe that an account can be given of the good for human beings and that justice is the ordering principle through which a society (or humanity) pursues that good. Justice as mutual advantage proposes that the rules of justice can be derived from the rational agreement of each agent to cooperate with others to further their own self-interest.

1 Retributive justice
There is general agreement that a just punishment should meet the following criteria. First, it should be imposed only on a properly convicted wrongdoer. Second, the quantum of suffering should satisfy the principle of ordinal proportionality. This means people convicted of crimes of equal seriousness should receive punishments of equal severity except where mitigating or aggravating circumstances alter the culpability of the offender. Third, the quantum of suffering should satisfy the principle of cardinal proportionality: there should be a vertical ranking of crimes and penalties by seriousness.

There is, however, disagreement over the justification for punishment, and this makes it controversial how 'seriousness', 'severity' and 'culpability' are assessed and how the scale of penalties

should be fixed. Those who appeal to deterrence may regard a widespread and socially disruptive crime as serious (whatever its degree of moral wrongness), and favour a scale of penalties designed to deter criminality. Those who favour retribution, however, have traditionally regarded seriousness as a factor of moral culpability and the scale of penalties as being derived from some notion of desert (see CRIME AND PUNISHMENT).

2 Conventionalism

Turning to social, or distributive, justice, the attraction of some form of conventionalist approach is clear. Since there are institutions, conventions and systems of law that determine what is due to whom, resolving issues of justice may be thought merely to require reading off the correct answer from such sources. The earliest extant statement of a conventionalist view of justice is offered by Socrates' interlocutors, Cephalus and Polemarchus, in Book I of Plato's *Republic*. Polemarchus states that justice is giving a man his due, or what is appropriate to him, and it is clear that for Polemarchus what is appropriate to each person is dictated by the conventions prevalent in contemporary Athenian society.

A modern statement of conventionalism has been offered by Michael Walzer, who has argued that every social good (for example, health care, education or political rights) has an appropriate criterion of distribution which is internally related to how that good is understood by society. For example, in the UK (as elsewhere), health care is understood essentially to concern itself with illness and the restoration of health. This shared understanding of health care is claimed by Walzer to entail a distributive criterion: medical need. Anyone, therefore, who claims that health care in the UK (and many other societies) ought to be distributed in accordance with, say, ability to pay has either failed to grasp the nature of the good of health care or falls outside the community which is united and defined by its shared understandings. The only universal principle of distributive justice is the demand that respect be given to different shared understandings: no community ought to impose its own understanding of a given good, and its criterion for the distribution of that good, on any other community with different views. However, it is doubtful that any society is so homogeneous as to boast a single, coherent and uncontested understanding of the meaning of each of its social goods; and even if it existed, it might not determine the particular distribution. Even if both requirements are met, it still makes sense to ask if this distribution is just. For example, a society marked by gross inequalities based on ascription at birth can surely be regarded as unjust on the basis of ideas not available to that society. It is when one asks why things are as they are that the philosophical problem of justice really begins.

3 Teleology

In the history of thought about justice, the most common justification of any given set of laws, conventions or practices has been that they are conducive to the furtherance of some good. For example, it may be held that there is a natural law which is knowable through the faculty of human reason (see NATURAL LAW). This tradition, owing its origins to the Greek Stoics, found its most lucid interpreter in CICERO and was given its definitive Christian form by AQUINAS (§13). 'True law', writes Cicero, 'is right reason in agreement with nature; it is of universal application, unchanging and everlasting'(*De republica c.*54–51 BC: III, XXII, 211). The link to human nature via human reason is important, for it then follows that human beings reach their true end, or realize their true nature, only by living in accordance with natural law. What justice is and why it is a good are, thus, answered at the same time.

A major problem for this account is its reliance on an external source. Cicero is typical in claiming in the same passage that it is God who 'is the author of this law, its promulgator, and its enforcing judge'. Natural law theory faces the difficulty of having to give an account of the existence and verifiability of the 'true and unchanging' moral order. Commonly, the natural law was conveniently said to underwrite the existing positive law: this may reflect the role of the powerful both in formulating positive law and defining natural law.

Suppose we are attracted to the notion that human institutions are to be justified by their contribution to human good, but do not believe that human reason is capable of discerning a divine plan. Then we may naturally arrive at the secular alternative embodied in utilitarianism: that the ground of justification is human wellbeing, happiness or 'utility'. When the utility of different people conflicts, the criterion for bringing their interests into relationship with one another is that aggregate utility is to be maximized (see UTILITARIANISM). However the classical utilitarians did not equate justice with utility maximization, but claimed, rather, that familiar rules of justice can be given utilitarian foundations.

Thus, David HUME (§12), in *A Treatise of Human Nature* (1739–40), described justice as an 'artificial virtue' in that individual acts of justice contribute to utility not directly (as an act of benevolence would)

but indirectly *qua* adherence to an institution that is on the whole beneficial. Hume's examples were respect for property, chastity (in women), allegiance to the government and promise-keeping. For Hume, then, justice was a convention – but it made sense to ask what good was served by following it. On somewhat parallel lines, J.S. Mill (§11) argued in *Utilitarianism* (1861) that 'justice' is the name we give to those precepts whose strict observance is important for the furtherance of the utilitarian end. Thus, utilitarians argue that the arbitrary departures from social rules summoned up by anti-utilitarians as an implication of the doctrine are, in the long term, not really for the general good. Opponents of utilitarianism however have claimed that situations might still arise in which injustice (as normally understood) would be for the general good.

4 Justice as mutual advantage

If we doubt that people can be motivated by a belief in natural law or a desire to act in ways that advance the general good, we can fall back on the idea that justice is a set of constraints that is more advantageous to each individual than the unrestrained pursuit of one's ends. Versions of 'justice as mutual advantage' can be found in Thrasymachus' 'might is right' argument in Book I of Plato's *Republic* and in the fraudulent social contract identified by Rousseau in his *Discourse on Inequality* (1755: Part II) as having been perpetrated by the rich on the poor. But the *locus classicus* of this theory is undoubtedly *Leviathan* by Thomas Hobbes (§7).

If the terms of agreement are to be to the advantage of each (compared with unrestrained conflict), they must reflect the relative bargaining strengths of the cooperators. The strong and talented have little to gain (or to fear) from the weak or infirm, and the latter may even 'fall beyond the pale' of morality if the strong have no reason for taking their interests into account, as David Gauthier makes clear in a contemporary restatement of the doctrine. Intuitively, it may seem perverse to call this a theory of justice. It is true that justice as mutual advantage has much of the structure of a theory of justice in that it results in rules that constrain the pursuit of self-interest. But the content of those rules will correspond to those of ordinary ideas of justice only if a rough equality of power holds between all the parties.

Even if this objection is not regarded as decisive, the theory suffers from internal problems. These concern the determinacy of the rules and their stability. The determinacy problem arises because of the necessity for all to start from a common view of the relative bargaining strengths of the participants. This is an immensely demanding condition, given the information about resources required and the different predictions that are liable to be made about the outcome of conflict. Even after rules have been agreed, some parties will have reason to press for changes if their bargaining power increases. Justice as mutual advantage results in rules which are no more than truces and, like truces, they are unlikely to be stable if there are changes in the balance of power between the sides (Barry 1995: 41).

Stability will also be challenged by the problem of non-compliance. Justice as mutual advantage appeals to the self-interest of each and does so by establishing rules that, if generally complied with, will further the interests of all individuals. However, this gives the agent no reason to comply with a given rule when there is greater advantage to be had by breaking it. This applies especially when the agent can free ride on the compliance of others. All that can be attempted is to increase the costs of non-compliance by increasing the sanctions if the agent is detected. To run a society using only self-interest and sanctions, however, would mean using a degree of coercion and of 'policing' hitherto unthought of in even the most totalitarian society.

5 Egalitarian justice

Egalitarian theories of justice start, like those of justice as mutual advantage, from the premise that the role of justice is to provide a framework within which people with competing ideas of the good can live together without conflict but they insist that the framework must reflect a commitment to equal treatment or equal consideration.

The accounts of the content of justice that are compatible with this covers a wide range: Robert Nozick's entitlement theory and John Rawls' theory of justice, for example, come to very different conclusions about what justice demands, even though both start with the basic idea that justice is to regulate the interactions of free and equal persons. Nozick claims that each person has a set of inviolable rights, and in this sense is treated equally. From this starting point he generates what he calls an entitlement theory of justice (see Nozick, R.). The just pattern of distribution is that which would result from voluntary transfers, given that holdings were justly acquired in the first place (by just transfer or by an appropriation that makes no one else worse off). Nozick, then, regards the claim to an equal set of absolute rights as defining the limits of justice: any actions which interfere with those rights (such as redistribution) are unjust no matter what the pattern or outcome of the entitlement theory. Nozick does not,

however, offer any account of the existence of such robust rights, and his arguments from intuition to show that any interference with individual rights is unjust are unconvincing. It is plausible that injustice may result from a large number of individual transactions each of which taken separately seems just.

John Rawls, in his classic work *A Theory of Justice* (1971), argues that justice requires the provision of equal basic liberties and fair opportunities for all, and that social and economic inequality can only be justified where it is to the benefit of the least advantaged. These two principles are derived by arguing that they would be chosen by free persons in an 'original position', the specifications of which prevent people from making unfair use of their natural and social advantages (see CONTRACTARIANISM; RAWLS, J. §1). Rawls then, in contrast to Nozick, believes that justice requires us to do much more for people than merely provide them with absolute property rights. Rather, the pattern of distribution is set at that which will maximally benefit the worst off, subject to the proviso that people are free to choose their own occupations, work effort, etc.

Rawls' original position has been criticized for reducing the choice of principles to an individual computation because the veil of ignorance entails that the participants are identical. Moreover, the priority of the worst off as the unique outcome depends on an extreme risk aversion on the part of the chooser. An alternative to Rawls' original position is to posit participants who are aware of their identities and motivated to seek agreement on terms that nobody could reasonably reject. Such a position has been proposed as an ethical theory by Thomas Scanlon in his *What We Owe to Each Other* (1998) and developed into a theory of justice by Brian Barry in his *Justice as Impartiality* (1995) (see CONTRACTARIANISM).

All theories of egalitarian justice face the problems of grounding the commitment to the fundamental equality of persons and giving an account of each agent's motivation to behave justly. Rawls offers two justifications for his principles. The first is that we can come to a 'reflective equilibrium' in which the principles arising from a correctly specified original position can be brought into line with our moral intuitions. The second justification is offered as a Kantian interpretation. On this account the original position provides a 'procedural interpretation' of Kant's realm of the 'kingdom of ends' (see KANT, I. §9). The original position and the choice of the principles are viewed as an attempt to replicate Kant's reduction of morality to autonomy and autonomy to rationality. Thus, by living in accordance with justice we realize our true natures as autonomous beings. This provides the motivation required.

In later papers and in his second book, *Political Liberalism* (1993), Rawls has conceded that the Kantian interpretation requires a controversial metaphysics and that it commits him to a particular view of the good life as autonomy. Instead he now emphasizes that his theory relies on nothing more than ideas 'latent in the public political culture' of modern Western democratic states. However, this raises the problem that many political cultures are inconsistent with Rawls' principles. In his subsequent *The Law of Peoples* (1999) he accepted the implication that the arguments for these principles will not be compelling for those whose political culture does not already have these ideas latent within it. This entails that some societies that violate fundamental equality can be just. It is thus incompatible with a commitment to equal treatment or equal consideration. Egalitarian theorists of justice, however, maintain that these are universally valid for all societies, and thus reject the conventionalist turn taken by Rawls' later thinking.

Meanwhile, there have been attempts to refine and extend the theory of egalitarian justice and to explore new ways of implementing its requirements. Thus, the concept of equal treatment within a society with a plurality of religious beliefs and cultural norms has come under scrutiny. Rules of apparently general application may in fact have a sharply differential impact on members of different groups. For example, uniform codes of dress and personal appearance may be incompatible with Sikh turbans, Muslim standards of female modesty or Rastafarian dreadlocks. Unless these codes can be justified as inherent necessities (perhaps hard hats on building sites), they constitute injustice in that they fail to provide equal treatment. Conversely, some egalitarian theorists have questioned some existing accommodations of religious beliefs or cultural norms on the ground that the price of equal treatment in this sense is too high. For example, permitting kosher and halal butchery enables orthodox Jews and Muslims to eat meat, but it has been argued that it inflicts unnecessary suffering and that this should be the decisive consideration.

This question can be posed in terms of responsibility: how far are members of different cultural groups responsible for adapting their behaviour to fit in with rules based on, for example, hygiene, safety or avoidance of cruelty, and how far do societies have a responsibility for ensuring that their rules do not put members of some cultures at a disadvantage in pursuing their ends? Much of post-Rawlsian egalitarian theory has been concerned with the relation between responsibility and equal treatment. Thus, a generalized form of the problem already

discussed can be put as follows: have people been treated equally if they have equal resources, or is this unfair to those who do not gain as much satisfaction from an equal share of equal resources as others do, because they have 'expensive tastes'? Does equal treatment instead require that those with 'expensive tastes' should have a larger share of resources?

An important question relating responsibility to equal treatment has been raised in the following terms: when have we 'done enough' to save our fellow citizens from making choices (perhaps out of ignorance) that pose serious risks to them? For example, how far should we regard 'unhealthy lifestyles' as the responsibility of individuals, and how far are societies responsible for providing information, ensuring the availability of 'healthy' alternatives and reducing levels of stress at work or in life generally for which 'unhealthy' choices are palliatives?

One way of thinking about equal treatment and responsibility is to propose that, under conditions of equal opportunity, people are responsible for inequalities of outcome. But what conditions are required for equality of opportunity to obtain in a form that underwrites this conclusion? On a weak interpretation, it would be satisfied if jobs were filled by the best-qualified applicants, so that the selection process should not be subject to discrimination or personal connections. However, this would be compatible with extremely unequal opportunities to acquire valuable qualifications. An obvious response is to add that all schools should provide all children with an equal opportunity to attain the best educational outcomes of which they are capable provided they make enough effort to achieve them. However, this is still not enough, according to some egalitarian theorists, because home and neighbourhood environments provide different children with very unequal opportunities to take advantage of formal education. Computers, books and a quiet room for homework are obvious material advantages. But parents and peers also provide children with very unequal capacities for achievement. An intellectually stimulating environment, parental help and encouragement, and peer expectation make an enormous difference.

Early intervention, with nursery schools and kindergartens available to all children regardless of their parents' financial position, undoubtedly reduce the unequal capacities that children bring to school, but are clearly still inadequate to close the gap. Thus, the next move is to propose that educational provision should be unequal, with more intensive and better schooling being provided for those disadvantaged by environmental factors. John Roemer has proposed a way of thinking about the implications of this in his *Equality of Opportunity* (1998). According to this, members of a society can be divided into 'types' according to some criterion associated with advantage or disadvantage (e.g., race or ethnicity, gender) and equality of opportunity would then be achieved if the members of each 'type' finished up with the same distribution of some valued good (e.g., earnings). Unequal outcomes within types would then – provided that the types were genuinely homogenous with respect to advantage or disadvantage – correspond to differences among members of the type for which they could properly be held responsible. The potentially radical implications of this are illustrated by Roemer's conjecture that, even if Americans were divided into only two types – white and black – an equal earning profile would require very many times more money to be spent on black education than on white education.

Clearly, Roemer's proposal would raise problems of deciding how types should be defined and how to assign individuals to them. Alternative methods of achieving equal opportunity that have been advocated by egalitarian theorists of justice would act directly on the distribution of income and wealth. For example, Philippe Van Parijs, in his *Real Freedom for All* (1995) has argued that we should approach as far as possible a condition in which each person has an equal opportunity to fulfil their life plan. This opportunity should extend to those whose life plans preclude paid employment. These might include people who wish to devote themselves to caring for others (whether related or not), working for voluntary associations or pursuing unprofitable artistic careers. Such people would be entitled, as would everyone, to a 'basic income' sufficient to live on. Those who preferred to make more money would, as now, be free to do so. In response to the objection that many people would not wish to underwrite another's life spent surfing off Malibu, a number of supporters of basic income have suggested that the entitlement should be conditional upon 'participation', which could take a wide variety of forms. Differences in earning potential would therefore play a much smaller role in determining the range of opportunities open to people, because those with a low capacity for turning time into money would not be forced to take low-paid, degrading or dangerous jobs.

Another important source of unequal opportunity is unequal access to capital. A capital grant at, say, the age of eighteen has been proposed by egalitarian theorists in Britain and the United States, for example by Julian Le Grand and Bruce Ackerman, as a way of reducing this kind of unequal opportunity. Ackerman also argues that it is unfair for higher education to be subsidized while those

who do not go on to university receive no equivalent state benefit. A universal cash benefit which could either be used on higher education or in other ways to get started would equalize opportunities to that extent.

The egalitarian approach has then proved itself to be a fertile source of new ideas about the principles it entails and the public policy policies that might advance the realization of egalitarian justice.

6 Critics of justice

The discussion so far has proceeded on the assumption that justice is the principal virtue of institutions. The theories of justice examined here would explain this primacy in different ways: by appealing to the most important shared understandings, the most stringent demands of Nature or God, the conduciveness of justice to utility or civil peace, or the role of justice in providing a fair framework for the pursuit of different conceptions of the good. But all agree that, where justice conflicts with other values, those other values must give way.

This consensus has been challenged on the grounds that under ideal conditions justice would be unnecessary, and appeals to it would actually destroy valuable social relationships. Thus, a marriage in which the spouses were constantly arguing in terms of rights and duties would be less good than one in which mutual love created spontaneous harmony. By an extension of this sentimental line of thought, an ideal community would be one in which justice had been transcended by a spirit of what used to be called (until feminist scholars objected) fraternity. This is one strand in the thought of Marx, and it recurs in the work of some contemporary feminist and communitarian writers (see COMMUNITY AND COMMUNITARIANISM; FEMINIST POLITICAL PHILOSOPHY).

The theorists of justice discussed above would not necessarily dispute such claims. Both Hume and Rawls argued that there are 'circumstances of justice' that make justice necessary. These are precisely the conditions – conflicting demands for material goods and unreconcilable aspirations – that the critics of justice believe would be transcended by a sufficiently strong community spirit. The disagreement is not analytical but turns on the view taken of the possibility and the desirability of creating a community in which justice ceased to be the first virtue. The partisans of justice can point out that the theoretical assault on 'bourgeois morality' has provided the supposed justification for the most appalling violations of rights (for example, in China, Cambodia and the former USSR), and ask if there is any reason to suppose that other social experiments driven by the same animus would be any more benign.

JUSTICE, CORRECTIVE

In his treatment of justice Aristotle articulated a contrast between two forms of justice, corrective and distributive. The former deals with the rectification of an injustice inflicted by one person on another, the latter with the distribution of benefits or burdens. These forms of justice have differing structures. What informs distributive justice is the notion of comparison: a greater share goes to the more meritorious under the distributive criterion. What informs corrective justice is the notion of correlativity or mutuality: an injurer has inflicted wrongful harm on a victim if and only if the victim has suffered wrongful harm through the injurer's conduct. The parties, as doer and sufferer of the same injustice, are the active and passive poles of a single wrong, which the law rectifies by holding the perpetrator liable to the victim.

In recent decades corrective justice (along with its differentiation from distributive justice) has attracted the attention of legal theorists interested in tort law as a repository of normative judgments and insights about wrongful injuries. These theorists view the notion of correlativity as crucial for understanding the relationship between the plaintiff and the defendant. An emphasis on correlativity illuminates both the arguments that properly belong within a system of liability and the connection between corrective justice as a theoretical idea and legal liability as a familiar institutional practice.

JUSTIFICATION AND KNOWLEDGE, COHERENCE THEORY OF

See KNOWLEDGE AND JUSTIFICATION, COHERENCE THEORY OF

JUSTIFICATION, EPISTEMIC

The term 'justification' belongs to a cluster of normative terms that also includes 'rational', 'reasonable' and 'warranted'. All these are commonly used in epistemology, but there is no generally agreed way of understanding them, nor is there even agreement as to whether they are synonymous. Some epistemologists employ them interchangeably; others distinguish among them. It is generally assumed, however, that belief is the target psychological state of these terms; epistemologists are concerned with what it takes for a belief to be justified, rational, reasonable or warranted. Propositions, statements, claims, hypotheses and theories are also said to be justified, but these uses are best understood as derivative; to say, for example, that a theory is justified for an individual is to say that were that individual to believe the theory (perhaps for the right reasons), the belief would be justified.

Historically, the two most important accounts of epistemic justification are foundationalism and coherentism. Foundationalists say that justification has a tiered structure; some beliefs are self-justifying, and other beliefs are justified in so far as they are supported by these basic beliefs. Coherentists deny that any beliefs are self-justifying and propose instead that beliefs are justified in so far as they belong to a system of beliefs that are mutually supportive. Most foundationalists and coherentists are internalists; they claim that the conditions that determine whether or not a belief is justified are primarily internal psychological conditions (for example, what beliefs and experiences one has). In the last quarter of the twentieth century, externalism emerged as an important alternative to internalism. Externalists argue that one cannot determine whether a belief is justified without looking at the believer's external environment. The most influential form of externalism is reliabilism.

Another challenge to traditional foundationalism and coherentism comes from probabilists, who argue that belief should not be treated as an all-or-nothing phenomenon: belief comes in degrees. Moreover, one's degrees of beliefs, construed as subjective probabilities, are justified only if they do not violate any of the axioms of the probability calculus. Another approach is proposed by those who advocate a naturalization of epistemology. They fault foundationalists, coherentists and probabilists for an overemphasis on a priori theorizing and a corresponding lack of concern with the practices and findings of science. The most radical naturalized epistemologists recommend that the traditional questions of epistemology be recast into forms that can be answered by science.

An important question to ask with respect to any approach to epistemology is, 'what implications does it have for scepticism?' Some accounts of epistemic justification preclude, while others do not preclude, one's beliefs being justified but mostly false. Another issue is the degree to which the beliefs of other people affect what an individual is justified in believing. All theories of epistemic justification must find a way of acknowledging that much of what each of us knows derives from what others have told us. However, some epistemologists insist that the bulk of the history of epistemology is overly individualistic and that social conditions enter into questions of justification in a more fundamental way than standard accounts acknowledge.

K

KABBALAH

Kabbalah is the body of Jewish mystical writings which became important at the end of the twelfth century in Provence and has been taken up with varying degrees of enthusiasm in an attempt to explore the esoteric side of Judaism. There are two main forms of Kabbalah: one which concentrates on gaining knowledge of God through study of his name, and a theosophical tradition that approaches God through his impact on creation. On both accounts God is linked to the world through ten *Sefirot*, hypostatic numbers which mediate between the Infinite and this world and thus (among other functions) help to explain how a being who is entirely ineffable can produce so much variety as is observed in nature. God's willingness to relate to the world gives his creatures the possibility of personal knowledge of him, although this can be acquired only through difficult and strenuous spiritual exercises. The variety of works which the Kabbalists produced are a blend of philosophical and mystical ideas which attempt to explore the inner meaning of faith and represent a creative and influential stream that both draws upon and contributes to Jewish philosophy.

OLIVER LEAMAN

KANT, IMMANUEL (1724–1804)

Introduction

Immanuel Kant was the paradigmatic philosopher of the European Enlightenment. He eradicated the last traces of the medieval worldview from modern philosophy, joined the key ideas of earlier rationalism and empiricism into a powerful model of the subjective origins of the fundamental principles of both science and morality, and laid the ground for much in the philosophy of the nineteenth and twentieth centuries. Above all, Kant was the philosopher of human autonomy, the view that by the use of our own reason in its broadest sense human beings can discover and live up to the basic principles of knowledge and action without outside assistance, above all without divine support or intervention.

Kant laid the foundations of his theory of knowledge in his monumental *Critique of Pure Reason* (1781). He described the fundamental principle of morality in the *Groundwork of the Metaphysics of Morals* (1785) and the *Critique of Practical Reason* (1788), in the conclusion of which he famously wrote:

> Two things fill the mind with ever new and increasing admiration and awe, the more often and steadily reflection is occupied with them: *the starry heaven above me and the moral law within me.* Neither of them need I seek and merely suspect as if shrouded in obscurity or rapture beyond my own horizon; I see them before me and connect them immediately with my existence.
>
> (*Collected Works* 1900: 5. 161–2)

Kant tried to show that both the laws of nature and the laws of morality are grounded in human reason itself. By these two forms of law, however, he is often thought to have defined two incommensurable realms, nature and freedom, the realm of what is and that of what ought to be, the former of which must be limited to leave adequate room for the latter. Kant certainly did devote much space and effort to distinguishing between nature and freedom. But as he also says, in the *Critique of Judgment* (1790), it is equally important 'to throw a bridge from one territory to the other'. Ultimately, Kant held that both the laws of nature and the laws of free human conduct must be compatible because they are both products of human thought imposed by us on the data of our experience by the exercise of our own powers. This was clearly stated in his last book, *The Conflict of the Faculties* (1798):

> Philosophy is not some sort of science of representations, concepts, and ideas, or a science of all sciences, or anything else of this sort; rather, it is a science of the human being, of its representing, thinking, and acting – it should present the human being in all of its components, as it is and ought to be, that is, in accordance with its natural determinations as well as its relationship of morality and freedom. Ancient philosophy adopted an entirely inappropriate standpoint towards the human being in the world, for it made it into a machine in it, which as such had to be entirely dependent on the world or on external things and circumstances; it thus made the human being into an all but merely passive part of the world. Now the critique of reason has appeared and determined the human being to a thoroughly *active* place in the world. The human being itself is the original creator of all its representations and concepts and ought to be the sole author of all its actions.
>
> (7: 69–70)

Thus, Kant derived the fundamental principles of human thought and action from human sensibility, understanding, and reason, all as sources of our autonomy; he balanced the contributions of these principles against the ineliminable inputs of external sensation and internal inclination beyond our own control; and he strove both to demarcate these principles from each other and yet to integrate them into a single system with human autonomy as both its foundation and its ultimate value and goal. These were the tasks of Kant's three great critiques. In the *Critique of Pure Reason*, the essential forms of space, time and conceptual thought arise in the nature of human sensibility and understanding and ground the indispensable principles of human experience. He then argued that reason, in the narrow sense manifest in logical inference, plays a key role in systematizing human experience, but that it is a mistake to think that reason offers metaphysical insight into the existence and nature of the human soul, an independent world, and God. In the *Critique of Practical Reason* and *Groundwork*, however, he argued that reason as the source of the ideal of systematicity is the source of the fundamental law of morality and our consciousness of our own freedom, which is the source of all value, and that we can postulate the truth of the fundamental dogmas of Christianity, our own immortality and the existence of God, as practical presuppositions of our moral conduct but not as theoretical truths of metaphysics. In the *Critique of Judgment*, Kant argued that the unanimity of taste and the systematic organization of both individual organisms and nature as a whole could be postulated, again not as metaphysical dogmas but rather as regulative ideals of our aesthetic and scientific pursuits; he then went on to argue that it is through these ideals that we can tie together the realms of nature and freedom, because aesthetic experience offers us a palpable image of our moral freedom, and a scientific conception of the world as a system of interrelated beings makes sense only as an image of the world as the sphere of our own moral efforts. In many of his last writings, from *Religion within the Limits of Reason Alone* (1793) to his final manuscripts, the *Opus postumum*, Kant refined and radicalized his view that our religious conceptions can be understood only as analogies for the nature of human reason itself.

The Enlightenment began by attempting to bring even God before the bench of human reason – at the turn of the eighteenth century, both Shaftesbury in Great Britain and Wolff in Germany rejected voluntarism, the theory that God makes eternal truths and moral laws by fiat, and argued instead that we ourselves must know what is right and wrong before we could even recognize supposedly divine commands as divine. Kant completed their argument, concluding that the human being 'creates the elements of knowledge of the world himself, a priori, from which he, as, at the same time, an inhabitant of the world, constructs a world-vision in the idea' (*Opus postumum*, 21: 31).

1 Life and works

Immanuel Kant was born on 22 April 1724 in Königsberg, the capital of East Prussia. He was the child of poor but devout followers of Pietism, a

Lutheran revival movement stressing love and good works, simplicity of worship, and individual access to God. Kant's promise was recognized by the Pietist minister Franz Albert Schultz, and he received a free education at the Pietist gymnasium. At sixteen, Kant entered the University of Königsberg, where he studied mathematics, physics, philosophy, theology, and classical Latin literature. His leading teacher was Martin Knutzen (1713–51), who introduced him to both Wolffian philosophy and Newtonian physics, and who inspired some of Kant's own later views and philosophical independence by his advocacy of physical influx against the pre-established harmony of LEIBNIZ and Wolff. Kant left university in 1746, just as the major works of the anti-Wolffian Pietist philosopher Christian August Crusius were appearing. Kant's upbringing would have made him receptive to Crusius, and thus he left university imbued with the Enlightenment aims of Wolffian philosophy but already familiar with technical criticisms of it, especially with Crusius' critique of Wolff's attempt to derive substantive conclusions from a single and merely formal first principle such as the logical principle of non-contradiction (see WOLFF, C.).

On leaving university, Kant completed his first work, *Thoughts on the True Estimation of Living Forces* (1746, published 1749), an unsuccessful attempt to mediate between Cartesian and Leibnizian theories of physical forces. Kant then worked as a tutor, serving in households near Königsberg for the next eight years. When he returned to the university in 1755, however, he had several works ready for publication. The first of these was *Universal Natural History and Theory of the Heavens*, a much more successful scientific work than his first in which Kant argued for the nebular hypothesis, or origin of the solar system out of a nebular mass by purely mechanical means. The book was scarcely known during Kant's lifetime, however, so the French astronomer Pierre Laplace (1749–1827) developed his version of the nebular hypothesis (published 1796) independently, and the theory became known as the Kant-Laplace hypothesis only later. In 1755, Kant also published two Latin works, his MA thesis *A brief presentation of some thoughts concerning fire*, and his first philosophical work, *A new elucidation of the first principles of metaphysical cognition*, which earned him the right to offer lectures at the university as a *Privatdozent* paid directly by his students. The following year Kant published *The employment in natural philosophy of metaphysics combined with geometry, of which sample I contains the physical monadology*, which made him eligible for a salaried professorship, although he was not to receive one until 1770. In these years, Kant also published four essays on earthquakes and winds.

Kant began lecturing in the autumn of 1755, and to earn a living lectured more than twenty hours a week. His topics included logic, metaphysics, ethics, and physics, and he subsequently added physical geography, anthropology (Germany's first lectures so entitled), pedagogy, natural right and even the theory of fortifications. Except for one small essay on optimism (1759), he did not publish again until 1762, when another burst of publications began. He then published, all in German: *The False Subtlety of the Four Syllogistic Figures* (1762); *The Only Possible Argument in support of a Demonstration of the Existence of God* and *Attempt to Introduce the Concept of Negative Magnitudes into Philosophy* (1763); *Observations on the Feeling of the Beautiful and Sublime* and *Inquiry concerning the Distinctness of the Principles of Natural Theology and Morality* (1764), the latter of which was his second-place entry in a competition won by Moses MENDELSSOHN; *Dreams of a Spirit-Seer, elucidated by Dreams of Metaphysics* (1766); and *Concerning the Ultimate Ground of the Differentiation of Directions in Space* (1768). These publications earned Kant widespread recognition in Germany. During this period, Kant was deeply struck by the work of Jean-Jacques ROUSSEAU, especially by his *Social Contract* and the paean to freedom in *Émile* (both 1762). By this time Kant was also acquainted with the philosophy of David HUME, whose two *Enquiries* and other essays, but not *A Treatise of Human Nature*, were published in German as early as 1755.

Having unsuccessfully applied for several chairs at home while declining offers elsewhere, Kant was finally appointed Professor of Logic and Metaphysics in Königsberg in 1770. This event occasioned his inaugural dissertation, and last Latin work, *On the form and principles of the sensible and intelligible world*. Following correspondence about this work with Johann Heinrich Lambert, Johann Georg Sulzer, and Mendelssohn, however, Kant fell into another decade-long silence, broken only by a few progress reports to his recent student Marcus Herz and a few minor essays. Yet during this 'silent decade', Kant was preparing for his enormous body of subsequent works. Beginning in 1781, with the first edition of the *Critique of Pure Reason*, Kant released a steady torrent of books. These include: *Prolegomena to Any Future Metaphysics that shall come forth as Scientific*, an attempted popularization of the first *Critique*, in 1783; two essays, 'Idea for a Universal History from a Cosmopolitan Point of View' and 'What is Enlightenment?' in 1784; *The Groundwork of the Metaphysics of Morals* and four other essays in 1785; *The Metaphysical Foundations of Natural Science*, essays on 'The Conjectural Beginnings of Human History' and 'What Does it mean to Orient Oneself in Thinking?' and two other pieces in 1786; a

substantially revised second edition of the *Critique of Pure Reason* in 1787; in 1788, the *Critique of Practical Reason* and an essay on 'The Use of Teleological Principles in Philosophy'; the *Critique of the Power of Judgment* as well as an important polemic 'On a discovery according to which any new Critique of Pure Reason is rendered dispensable by an older one' in 1790; the political essay 'On the Common Saying: "That may be right in theory but does not work in practice"' and the controversial *Religion within the Limits of Reason Alone* in 1793; *Towards Perpetual Peace* in 1795; the *Metaphysics of Morals*, comprising the 'Doctrine of Right' and the 'Doctrine of Virtue', in 1797, as well as the essay 'On a putative Right to Lie from Love of Mankind'; and his last major works in 1798, a handbook on *Anthropology from a Pragmatic Point of View* and his defence of the intellectual freedom of the philosophical faculty from religious and legal censorship in the restrictive atmosphere of Prussia after Frederick the Great, *The Conflict of the Faculties*. (With Kant's approval, some of his other lecture courses were also published, including *Logic* in 1800 and *Physical Geography* and *Pedagogy* in 1804.) Kant retired from lecturing in 1797, at the age of seventy-three, and devoted his remaining years to a work which was to be entitled 'The Transition from the Metaphysical First Principles of Natural Science to Physics', but which was far from complete when Kant ceased working on it in 1803. (Selections from his drafts were first published in 1882–4, and they were first fully published as *Opus postumum* in 1936–8.) After a lifetime of hypochondria without any serious illness, Kant gradually lost his eyesight and strength and died 12 February 1804.

2 Kant's work to 1770

In his first work, *Living Forces*, Kant tried to mediate a dispute about the measurement of forces between Descartes and Leibniz by employing a distinction between 'living' or intrinsic forces and 'dead' or impressed ones to argue that Leibniz's measure was correct for the former and Descartes's for the latter. This distinction could not be maintained in a uniform mechanics, and the young Kant remained ignorant of the mathematically correct solution, which had been published by D'Alembert in 1743. Nevertheless, the work already showed Kant's lifelong preoccupation with the relation between scientific laws and metaphysical foundations. It also included the observation that the three-dimensionality of physical space is a product of actually existing forces, not the only geometry that is logically possible (1900: 10, 1: 24).

Kant's works of 1755 reveal more of his originality and his enduring themes. *Universal Natural History*, deriving the present state of the planets from postulated initial conditions by reiterated applications of the laws of Newtonian mechanics, manifests not only Kant's commitment to those laws, for which he was subsequently to seek philosophical foundations, but also his commitment to thoroughly naturalistic explanations in science, in which God can be the initial source of natural laws but never intervenes within the sequence of physical causes. *New Elucidation*, while not yet a methodological break from the rationalism of Leibniz, Wolff and Alexander Gottlieb Baumgarten (1714–62) (whose textbooks on metaphysics, ethics and aesthetics Kant used for decades), breaks with them on several substantive issues. Kant begins by rejecting Wolff's supposition that the principle of non-contradiction is a single yet sufficient principle of truth, arguing instead that there must be separate first principles of positive and negative truths; following Crusius, Kant was always to remain suspicious of programmes to reduce all truth to a single principle. Kant then criticized previous proofs of the Principle of Sufficient Reason, although his own proof was also a failure. More importantly, he argued that the principle of sufficient reason does not entail the theory of pre-established harmony drawn from it by the Leibnizians: the need for a sufficient reason for any change in a substance proves the necessity rather than impossibility of real interaction among a plurality of substances. Transposed into an epistemological key, this argument was to become central in the first *Critique*. The work is also noteworthy for the first suggestion of Kant's critique of Descartes's ontological argument for the existence of God (see God, arguments for the existence of), and for a first treatment of the problem of free will as well. Here Kant defended against the indeterminism of Crusius the determinism of Leibniz (see Determinism and indeterminism), although he was later to criticize this as the 'freedom of a turnspit' (5: 97). Kant's later theory of free will attempts to reconcile Crusius and Leibniz.

In the *Physical Monadology* (1756), Kant tries to reconcile the infinite divisibility of space in geometry with the need for simple, indivisible substances in metaphysics – the subsequent theme of the first *Critique*'s second Antinomy (see §8). Kant does not yet appeal to a metaphysical distinction between appearance and reality, but instead argues that because bodies in space are not ultimately composed of particles but of attractive and repulsive forces (1: 484), they may be physically indivisible even when space itself is still mathematically divisible.

Kant's works of the 1760s introduce some of the methodological as well as substantive assumptions of

his mature philosophy. *The Only Possible Argument* details Kant's attack upon the ontological argument, the paradigmatic rationalistic argument because of its presupposition that an existence-statement can be derived from the analysis of a concept. Kant argues that 'existence is not a predicate or a determination of a thing' (2: 72), but rather the 'absolute positing of a thing' (2: 73); that is, the existence of its subject is *presupposed* by the assertion of any proposition, not inferred from the concepts employed in it. Kant also maintains that the other rationalist argument for theism, the argument from the contingency of the world to a necessary cause of it, as well as the empiricists' favourite, the argument from design, fail to prove the existence of a necessary being with all the attributes of God. However, Kant still holds that the existence of God can be proved as a condition of the *possibility* of any reality. Finally, Kant further develops his argument that scientific explanation cannot allow divine intervention in the sequence of events, and that God must be seen only as the original ground of the laws of nature.

Negative Magnitudes announces a fundamental methodological break from rationalism. Inspired by both Crusius and Hume, Kant argues that *real opposition* (as when two velocities in opposite directions or a pleasure and a pain cancel each other out) is fundamentally different from *logical contradiction* (as between a proposition and its negation); he then applies this to causation, arguing that the *real ground* of a state does not entail its existence logically, but is connected to it in an entirely different way. This precludes any proof of the principle of sufficient reason from merely logical considerations alone (2: 202).

The *Inquiry into the Distinctness of the Principles of Natural Theology and Ethics* continues Kant's attack upon rationalism. The question for this essay was whether metaphysics could use the same method as mathematics, which Kant firmly denied: mathematics, he argues, can prove its theorems by constructing its objects from their very definitions, but metaphysics can only use analysis to tease out the definitions of its objects from given concepts, and cannot construct the objects themselves (2: 276). The claim that the method of philosophy is analysis may sound like rationalism; however, Kant insists that in both metaphysics and ethics philosophy needs *material* as well as *formal* first principles, again precluding any purely logical derivation of philosophical theses. Kant does not yet have a clear account of material first principles – he is sympathetic to Crusius's account of indemonstrable cognitions and to the suggestion of the moral sense theorists Shaftesbury and HUTCHESON that the first principles of ethics arise from *feeling*, but not satisfied with either. Without yet naming it, Kant also introduces his distinction between hypothetical and categorical imperatives (2: 298).

Still in 1764, however, the book *Observations on the Feeling of the Beautiful and Sublime* already announces Kant's departure from moral sense theory and introduces the most fundamental theme of Kant's ethics. Virtue cannot depend merely on benevolent inclination, but only on general principles, which in turn express 'a feeling that lives in every human breast and extends itself much further than over the particular grounds of compassion and complaisance . . . the *feeling of the beauty and dignity of human nature*' (2: 217). In notes in his own copy of this work, Kant went even further, and first clearly stated his enduring belief that 'freedom properly understood (moral, not metaphysical) is the supreme principle of all virtue as well as of all happiness' (20: 31).

In *Dreams of a Spirit-Seer*, Kant ridicules traditional metaphysics by comparing it to the fantasies of the Swedish theosophist Emmanuel Swedenborg; Kant argues instead that metaphysical concepts cannot be used without empirical verification, and that therefore metaphysics can at most be 'a science of the *boundaries of human reason*' (2: 368). The work also contains further thoughts on morality, suggesting that the two forces of egoism and altruism define the structure of the moral world in much the way that the forces of repulsion and attraction define that of the physical world (2: 334). But Kant does not yet argue that postulates of practical reason may be a valid alternative to the delusions of metaphysics.

Finally, the brief essay on *Directions in Space* argues that incongruent counterparts, such as right- and left-handed gloves, which have identical descriptions but cannot occupy the same space, prove that the qualities of objects are not determined by concepts alone but also by their relation to absolute space. Kant did not yet raise metaphysical questions about the nature of absolute space or epistemological questions about how we could know it, but this essay can be seen as introducing the distinction between intuitions and concepts which was to be a cornerstone of Kant's subsequent thought (see §5).

3 *The* Inaugural Dissertation *of 1770 and the problem of metaphysics*

Kant's *Inaugural Dissertation* of 1770 consolidated many of the gains he had made during the 1760s and introduced a fundamentally new theory about the metaphysics and epistemology of space and time which was to remain a constant in his subsequent thought, but also left open crucial questions about the source of our most fundamental concepts.

Although Kant hoped to proceed quickly to his projects in the philosophy of science and in moral and political theory, it was to take him all of the next decade to answer these preliminary questions.

Taking up where *Directions in Space* left off, Kant begins the dissertation with the distinction between intuitions (singular and immediate representations of objects) and concepts (general and abstract representations of them) as distinct but equally important elements in the '*two-fold genesis* of the concept [of a world] out of the nature of the mind'. The intellect (Kant does not yet divide this into understanding and reason) provides abstract concepts, under which instances are subordinated; the 'sensitive faculty of cognition' provides 'distinct intuition[s]' which represent concepts 'in the concrete' and within which different parts may be coordinated (1900: 2: 387). Kant goes on to claim that 'whatever in cognition is sensitive is dependent upon the special character of the subject', that is, the knower, so that sensation, through intuitions, represents things '*as they appear*' (*phenomena*), while the intellect, through concepts, represents things '*as they are*' (*noumena*) (2: 392). Kant then presents the 'principles of the form of the sensible world': time and space are the forms of the intuition of all objects (time is the form for all representation of objects, inner or outer, while space is the form for the representation of all outer objects) which do not arise from but are presupposed by all particular perceptions; they are singular rather than general, that is, particular times or spaces are parts of a single whole rather than instances of a general kind; and they must each be 'the subjective condition which is necessary, in virtue of the nature of the human mind, for the co-ordinating of all things in accordance with a fixed law', or a '*pure intuition*' rather than '*something objective and real*' (2: 398–400, 402–4). Only thus can we explain our knowledge of both these general claims about space and time as well as particular claims about their structure, such as the theorems of geometry (2: 404). In other words, we can explain the certainty of knowledge about space and time only by supposing that it is knowledge of the structure of our own minds, and thus of how objects appear to us, rather than knowledge about how things are in themselves. This necessarily subjective origin and significance of certainty, which Kant was later to name 'transcendental idealism', is the foundation for the active role of the human mind in knowledge of the world.

Kant has little to say about the source of intellectual concepts, but continues to believe that they give us knowledge of how things are independently of the structure of our own minds. His main claim, still Leibnizian, is that in order to conceive of things as genuinely distinct substances, yet as collectively interacting in a single world, we must conceive of them as contingent beings all depending upon a single necessary being (2: 407–8). Kant then argues that metaphysical error arises when the principles of sensitive and intellectual cognition are confused, but more particularly when 'the principles which are native to sensitive cognition transgress their limits, and affect what belongs to the intellect' (2: 411) – the opposite of what he will argue later when he claims that metaphysical illusion arises from thinking that human reason can reach beyond the limits of the senses (see §8). Finally, Kant introduces as mere 'principles of convenience' the principles of universal causation and of the conservation of substance as well as a more general 'canon' of rationality, that '*principles are not to be multiplied beyond what is absolutely necessary*' (30, 2: 418). A better account of these principles will occupy much of Kant's later work (see §7).

Early readers of Kant's dissertation objected to the merely subjective significance of space and especially time, but Kant was never to surrender this theory. What came to bother him instead was his inadequate treatment of metaphysical concepts such as 'possibility, existence, necessity, substance, cause, etc.' (2: 395). In a famous letter of 21 February 1772 to Marcus Herz (10: 129–35), Kant claimed that the 'whole secret' of metaphysics is to explain how intellectual concepts which neither literally produce their objects (as God's concepts might) nor are merely produced by them (as empirical concepts are) nevertheless necessarily apply to them. But Kant did not yet know how to answer this question.

His first progress on this issue is found in fragments from 1774–5 (Reflections 4674–84, 17: 643–73). Two key ideas are found here. First, Kant finally formulates the problem of metaphysics as that of 'synthetic' rather than 'analytic' propositions: how can we know the truth of propositions in which the predicates clearly go beyond anything contained in their subject-concepts but yet enjoy the same universality and necessity as propositions which are mere tautologies, whose predicates are contained in their subject concepts (17: 643–4, 653–5)? Second, Kant here first states that the answer to this question lies in recognizing that certain fundamental concepts, not just the intuitions of space and time, are 'conditions of the concrete representation [of objects] in the subject' (17: 644) or of the unity of '*experience* in general' (17: 658). Kant's idea is that in order to ground any determinate ordering of either subjective or objective states in temporal succession, we must use the concepts of substance, causation, and interaction, and that these must therefore be categories which originate in the understanding just as the pure forms of space and time originate in the sensibility.

4 *The project of the* Critique of Pure Reason

In spite of this progress in 1775, six more years passed before the *Critique of Pure Reason* finally appeared in 1781. In an umistakeable reference to Locke's *Essay concerning Human Understanding* (see Locke, J.), Kant began the work with the promise to submit reason to a critique in order to obtain a 'decision about the possibility or impossibility of metaphysics in general and the determination of its sources, its scope and its boundaries' (A xii). The 'chief question' would be 'what and how much can understanding and reason know apart from all *experience*?' (A xvii). Answering this question would require discovering the fundamental principles that human understanding contributes to human experience and exposing the metaphysical illusions that arise when human reason tries to extend those principles beyond the limits of human experience.

But Kant's project was even more ambitious than that, as he was to make clear in the revised edition of the *Critique* six years later. There, in addition to more explicitly describing his strategy for explaining the certainty of the first principles of human knowledge as one of supposing that 'objects must conform to our knowledge' rather than vice versa (B xvi), Kant described his whole project in broader terms: 'I therefore had to deny *knowledge* in order to make room for *faith*' (B xxx). Kant did not mean to return to the sceptical fideism of earlier thinkers such as Pierre Bayle, who simply substituted religious belief for theoretical ignorance. Instead, Kant argues first that the human mind supplies necessary principles of sensibility and understanding, or perception and conception; next, that if human reason tries to extend the fundamental concepts and principles of thought beyond the limits of perception for purposes of theoretical knowledge, it yields only illusion; but finally that there is another use of reason, a practical use in which it constructs universal laws and ideals of human conduct and postulates the fulfilment of the conditions necessary to make such conduct rational, including the freedom of the will, the existence of God, and the immortality of the soul. This use of reason does not challenge the limits of theoretical reason but is legitimate and necessary in its own right.

In the Introduction, Kant defines his first task as that of explaining the possibility of synthetic a priori judgments. This notion is grounded in two distinctions. First, there is a logical distinction between analytic and synthetic propositions: in analytic propositions, the predicate-concept is implicitly or explicitly contained in the subject-concept (for example, 'A bachelor is unmarried' or 'An unmarried male is male'), so the proposition conveys no new information and is true by identity alone; in synthetic propositions, the content of the predicate is clearly not contained in the subject-concept (for example, 'Bachelors are unhappy') (A 6–7/B 10–11), so the proposition conveys new information and cannot be true by identity alone. Second, there is an epistemological distinction between propositions which are a posteriori, or can be known to be true only on the basis of antecedent experience and observation, and those which are a priori, or known to be true independently of experience, or at least any particular experience (A 1–2/B 1–3). Kant maintains that anything which is known to be universally and necessarily true must be known a priori, because, following Hume, he assumes that experience only tells us how what has actually been observed is, not how everything must be (A 1–2/B 3–4). Combining these two distinctions yields four possible kinds of judgments. Two of these obviously obtain: analytic a priori judgments, in which we know a proposition to be true by analysis of its subject-concept and without observation; and synthetic a posteriori judgments, in which we know factual statements going beyond subject-concepts to be true through observation. Equally clearly, a third possibility is excluded: there are no analytic a posteriori judgments, for we need not go to experience to discover what we can know from analysis alone. What is controversial is whether there are synthetic a priori judgments, propositions that are universally and necessarily true, and thus must go beyond experience, but which cannot be reached by the mere analysis of concepts. Both rationalists and empiricists had denied such a possibility, but for Kant only it could ground an informative science of metaphysics at all.

Kant's notion of synthetic a priori judgment raises various problems. Critics have long complained that Kant provides no unequivocal criterion for deciding when a predicate is contained in a subject, and twentieth-century philosophers such as W.V. Quine argued that there are no analytic truths because not even definitions can be held entirely immune from revision in the face of empirical facts. Lewis White Beck showed, however, that this did not affect Kant's project, for Kant himself, in a polemic with the Wolffian Johann August Eberhard, argued that analysis always presupposes synthesis, and that the adoption of any definition itself has to be justified, either by construction or observation; so even conceding that all judgments are ultimately synthetic, Kant's question remains whether any of these are synthetic a priori.

Another issue is just what synthetic a priori judgments Kant intended to justify. In the 'Prolegomena' and the 'Introduction' to the second edition of the *Critique*, Kant suggests that it is

obvious that synthetic a priori judgments exist in what he calls 'pure mathematics' and 'pure physics', and that his project is to show that what explains these also explains other such propositions, in metaphysics. Elsewhere, however, Kant suggests that metaphysics must show that there are any synthetic a priori judgments, even in mathematics and physics. While much of the content of the *Critique* suggests that Kant's considered view must be the latter, he is far from clear about this.

5 Space, time and transcendental idealism

The first part of the *Critique*, the 'Transcendental Aesthetic', has two objectives: to show that we have synthetic a priori knowledge of the spatial and temporal forms of outer and inner experience, grounded in our own pure intuitions of space and time; and to argue that transcendental idealism, the theory that spatiality and temporality are only forms in which objects appear to us and not properties of objects as they are in themselves, is the necessary condition for this a priori knowledge of space and time (see SPACE; TIME).

Much of the section refines arguments from the inaugural dissertation of 1770. First, in what the second edition labels the 'Metaphysical Exposition', Kant argues that space and time are both *pure forms of intuition* and *pure intuitions*. They are pure *forms* of intuition because they must precede and structure all experience of individual outer objects and inner states; Kant tries to prove this by arguing that our conceptions of space and time cannot be derived from experience of objects, because any such experience presupposes the individuation of objects in space and/or time, and that although we can represent space or time as devoid of objects, we cannot represent any objects without representing space and/or time (A 23–4/B 38–9; A 30–1/B 46). They are pure *intuitions* because they represent single individuals rather than classes of things; Kant tries to prove this by arguing that particular spaces and times are always represented by introducing boundaries into a single, unlimited space or time, rather than the latter being composed out of the former as parts, and that space and time do not have an indefinite number of instances, like general concepts, but an infinite number of possible parts (A 24/B 39–40; A 31–2/B 47–8).

Next, in the 'Transcendental Exposition', Kant argues that we must have an a priori intuition of space because 'geometry is a science which determines the properties of space synthetically and yet a priori' (B 40). That is, the propositions of geometry describe objects in space, go beyond the mere concepts of any of the objects involved – thus geometric theorems cannot be proved without actually constructing the figures – and yet are known a priori. (Kant offers an analogous but less plausible argument about time, where the propositions he adduces seem analytic (B 48).) Both our a priori knowledge about space and time in general and our synthetic a priori knowledge of geometrical propositions in particular can be explained only by supposing that space and time are of subjective origin, and thus knowable independently of the experience of particular objects.

Finally, Kant holds that these results prove transcendental idealism, or that space and time represent properties of things as they appear to us but not properties or relations of things as they are in themselves, let alone real entities like Newtonian absolute space; thus his position of 1768 is now revised to mean that space is epistemologically but not ontologically absolute (A 26/B 42; A 32–3/B 49–50; A 39–40/B 56–7). Kant's argument is that 'determinations' which belong to things independently of us 'cannot be intuited prior to the things to which they belong', and so could not be intuited a priori, while space and time and their properties *are* intuited a priori. Since they therefore cannot be properties of things in themselves, there is no alternative but that space and time are merely the forms in which objects appear to us.

Much in Kant's theory has been questioned by later philosophy of mathematics. Kant's claim that geometrical theorems are synthetic because they can only be proven by construction has been rendered doubtful by more complete axiomatizations of mathematics than Kant knew, and his claim that such propositions describe objects in physical space yet are known a priori has been questioned on the basis of the distinction between purely formal systems and their physical realization.

Philosophical debate, however, has centred on Kant's inference of transcendental idealism from his philosophy of mathematics. One issue is the very meaning of Kant's distinction between appearances and things in themselves. Gerold Prauss and Henry Allison have ascribed to Kant a distinction between two kinds of *concepts* of objects, one including reference to the necessary conditions for the perception of those objects and the other merely leaving them out, with no ontological consequences. Another view holds that Kant does not merely assert that the concepts of things in themselves lack reference to spatial and temporal properties, but actually denies that things in themselves are spatial and temporal, and therefore maintains that spatial and temporal properties are properties only of our own representations of things. Kant makes statements that can support each of these interpretations; but proponents of the second view, including the present author, have argued that

it is entailed by both Kant's argument for and his use of his distinction, the latter especially in his theory of free will (see §8).

The debate about Kant's argument for transcendental idealism, already begun in the nineteenth century, concerns whether Kant has omitted a 'neglected alternative' in assuming that space and time must be *either* properties of things as they are in themselves or of representations, but not both, namely that we might have a priori knowledge of space and time because we have an a priori subjective representation of them while they are also objective properties of things. Some argue that there is no neglected alternative, because although the *concepts* of appearances and things in themselves are necessarily different, Kant postulates only one set of *objects*. This author has argued that the 'neglected alternative' is a genuine possibility that Kant intends to exclude by arguing from his premise that propositions about space and time are *necessarily* true: if those propositions were true *both* of our own representations and of their ontologically distinct objects, they might be necessarily true of the former but only contingently true of the latter, and thus not necessarily true throughout their domain (A 47–8/B 65–6). In this case, however, Kant's transcendental idealism depends upon a dubious claim about necessary truth.

6 Pure concepts of the understanding

The 'Transcendental Analytic' of the *Critique* breaks new ground, arguing that the most fundamental categories of thought as well as the forms of perception are themselves human products which are necessary conditions of the possibility of experience. Like the 'Transcendental Aesthetic', its first section, the 'Analytic of Concepts', is also divided into a 'metaphysical' and a 'transcendental deduction' (B 159).

In the metaphysical deduction Kant intends to provide a principle to identify the most fundamental concepts of thought, the categories of the understanding, and then to show that our knowledge of any object always involves these categories. The key to his argument is the claim that knowledge is always expressed in a *judgment* (A 68–9/B 93–4); he then argues that there are certain characteristic forms or 'logical functions' of judgment, and that in order for our judgments to be about objects, these logical functions of judgments must also provide the basic concepts for conceiving of objects. Thus Kant first produces a table of the logical functions of judgment, based on the premise that every judgment has a *quantity*, *quality*, *relation* and *modality*, and then produces a table of categories, under the same four headings, showing how objects of such judgments must be conceived. Thus, judgments may be universal, particular, or singular, and then their objects must be unities, pluralities, or totalities; judgments may be affirmative, negative, or infinite, and objects manifest either reality, negation, or limitation; judgments may relate a predicate to a subject (categorical judgment), or else relate one predicate-subject judgment to another as antecedent and consequent (hypothetical judgment) or as alternatives (disjunctive judgment), and objects may correspondingly manifest the relations of inherence and subsistence, causality and dependence, or community or reciprocity; finally, judgments may be problematic, assertoric, or apodeictic, thus their objects either possible or impossible, existent or non-existent, or necessary or contingent (A 70/B 95; A 80/B 106).

Kant's scheme is intuitively plausible, and he makes use of it throughout his works. But philosophers as diverse as HEGEL and Quine have questioned its coherence and necessity. What is troubling for Kant's own project, however, is that he does not show why we must use all the logical functions of judgment, hence why we must use all the categories. In particular, he does not show why we must make not only categorical but also hypothetical and disjunctive judgments. Without such a premise, Kant's arguments for causation, against Hume, and for interaction, against Leibniz, are not advanced. It is unclear whether Kant recognized this defect in the argument of the metaphysical deduction. But he addressed precisely this problem in the subsequent chapter on the 'System of all Principles of Pure Understanding', which does attempt to demonstrate the necessity of the use of each of the categories. This chapter will be discussed in the following section

Kant's aim and his strategy in the transcendental deduction remain debatable, despite his complete revision of this section in the second edition of the *Critique*. Some view the transcendental deduction as a 'regressive argument' aimed at empiricism, meant to show only that *if* we make judgments about objects then we must use a priori concepts. But if Kant already established this in the metaphysical deduction, the transcendental deduction becomes redundant. It seems more natural to see the latter as intended to fix the *scope* of our use of the categories by showing that we can have *no* experience which is immune from conceptualization under them, thus that the categories enjoy universal objective validity. Because these categories originate in the logical structure of our own thought, Kant holds, we must conceive of ourselves as the autonomous lawgivers for all of nature (A 127–8B 164).

There are many differences between the two versions of the transcendental deduction, but both

employ the fundamental idea that we cannot have some form of *self*-consciousness, or 'transcendental apperception', without also having consciousness of *objects*, which in turn requires the application of the categories; then, since Kant holds that we can have no experience at all without being able to be conscious that we have it, he can argue that we can have no experience to which we cannot apply the categories. The success of this strategy is unclear. The first-edition deduction begins with a debatable analysis of the necessary conditions for knowledge of an object, which slides from the conditional necessity that we must use rules if we are to have knowledge of objects to an absolute necessity that we must have knowledge of objects, and then introduces transcendental apperception as the 'transcendental ground' of the latter necessity (A 106). In the second edition, Kant begins directly with the claim that self-consciousness of our experience is always possible, which has not met with much resistance, but then makes the inference to the necessity of knowledge of objects conceived of through the categories by equating transcendental apperception with a notion of 'objective apperception' that is equivalent to judgment about objects (B 139–40). This makes the connection between self-consciousness and the categorial judgment of objects true by definition, and undermines Kant's claim to provide a synthetic rather than analytic proof of the objective validity of the categories.

In spite of these problems, the idea that self-consciousness depends upon knowledge of objects and thus on the use of the categories to conceive of objects has remained attractive; and some of the most interesting recent work on Kant has been reconstructions of the transcendental deduction, such as those by Peter Strawson, Jonathan Bennett and Dieter Henrich. Others have concluded that Kant only establishes a convincing connection between self-consciousness and categorial thought of objects once he shows that making judgments about objects, using the categories, is a necessary condition for making judgments about the *temporal* order of our experience. This is Kant's project in the next section of the *Critique*.

7 The principles of judgment and the foundations of science

Kant proceeds from the categories to the foundations of natural science in several steps. First, he argues that the categories, which thus far have merely logical content, must be made 'homogeneous' with experience, or be recast in forms we can actually experience. Since time, as the form of both outer and inner sense, is the most general feature of our sensible experience, Kant argues that the categories must be made homogeneous with experience by being associated with certain determinate temporal relations or 'schemata' (A 138–9/B 177–8). For example, the pure category of ground and consequence, thus far understood only abstractly as the relation of the states of objects that makes them fit to be objects of hypothetical ('if-then') judgments, is associated with the schema of rule-governed temporal succession, something closer to what we can actually experience. Focused as he is on the universality of time, Kant seems to de-emphasize spatiality unduly in the 'Schematism': for example, it would seem more natural to say that the schema of causality is the rule-governed temporal succession of states of objects within an appropriate degree of spatial contiguity.

Next, in the 'System of all Principles of Pure Understanding', Kant argues for the necessity of certain fundamental principles of all natural laws. Following the division of the categories, this chapter is divided into four parts. In the first, the 'Axioms of Intuition', Kant argues that 'All intuitions are extensive magnitudes' (B 202), and thus that all objects of experience can be represented as wholes consisting of homogeneous parts, and thus can be represented mathematically as sums of such units. In the second, the 'Anticipations of Perception', Kant proves that 'In all appearances, the real that is an object of sensation has intensive magnitude, that is, a degree' (B 207). Here he argues that sensations can be assigned a numerical measure that does not represent a sum of separable parts, but rather a position on a scale of intensity, and then infers that because our sensations manifest varying degrees of intensity we must also conceive of the qualities of objects that they represent as manifesting a reality that varies in degree. The first of these two 'mathematical' principles (A 162/B 201) does not add to results already established in the Transcendental Aesthetic, however, and the second depends upon an empirical assumption.

In the next section, the 'Analogies of Experience', dealing with the first of two kinds of 'dynamical' principles, Kant offers some of the most compelling and important arguments in the *Critique*. In the First Analogy, Kant argues that we can determine that there has been a change in the objects of our perception, not merely a change in our perceptions themselves, only by conceiving of what we perceive as successive states of enduring substances (see SUBSTANCE). Because we can never perceive the origination or cessation of substances themselves, but only changes in their states, Kant argues, the sum-total of substances in nature is permanent (B 224). In the Second Analogy, Kant argues for a further condition for making judgments about change in objects: because even when we

undergo a sequence of perceptions, there is nothing in their immediate sensory content to tell us that there is an objective change, let alone what particular sequence of change there is, we can only distinguish a '*subjective sequence* of apprehension from the *objective sequence* of appearances' (A 193/B 238) by judging that a particular sequence of objective states of affairs, *a fortiori* the sequence of our perceptions of those states, has been determined in accordance with a rule that states of the second type can only follow states of the first type – precisely what we mean by a causal law. Finally, the Third Analogy argues that because we always perceive states of objects successively, we cannot immediately perceive states of two or more objects to be simultaneous, and can therefore only judge that two such states simultaneously exist in different regions of space if they are governed by laws of interaction dictating that neither state can exist without the other (A 213/B 260).

Kant's arguments have been assailed on the basis of relativity theory and quantum mechanics. But since they are epistemological arguments that our ability to make temporal judgments about the succession or simultaneity of states of affairs depends upon our judgments about substance, causation and interaction, it is not clear that they are open to objection from this quarter. If relativity tells us that the succession or simultaneity of states of affairs may depend upon the choice of inertial frame, then Kant's theory is not refuted, but merely predicts that in that case our own judgments about temporal sequence must also vary. If quantum mechanics tells us that causal laws are merely probabilistic, then Kant's theory is again not refuted but just predicts that in that case our temporal judgments cannot be entirely determinate.

In the last section of the 'Principles', Kant assigns empirical criteria to the modal concepts of possibility, actuality and necessity. The main interest of this section lies in the 'Refutation of Idealism' which Kant inserted into it in the second edition. Here Kant argues that temporal judgments about one's own states require reference to objects which endure in a way that mental representations themselves do not, and therefore that consciousness of oneself also implies consciousness of objects external to oneself (B 275–6; also B xxxix–xli). There has been controversy not only about the precise steps of the proof, but also about whether it is supposed to prove that we have knowledge of the existence of things ontologically distinct from our own representations, which seems to undercut Kant's transcendental idealism. However, the argument of 1787 was actually just the first of many drafts Kant wrote (Reflections 6311–16, 18: 606–23), and these suggest that he did mean to prove that we know of the existence of objects ontologically distinct from ourselves and our states, although we cannot attribute to them as they are in themselves the very spatiality by means of which we represent this ontological distinctness.

Finally, in the *Metaphysical Foundations of Natural Science*, published between the two editions of the *Critique* (1786), Kant carried his a priori investigation of the laws of nature one step further by introducing not only the empirical notion of change itself but also the further empirical concept of matter as the movable in space (1900: 4: 480). With this one empirical addition, he claims, he can deduce the laws of phoronomy, the vectorial composition of motions in space; of dynamics, the attractive and repulsive forces by which space is actually filled; of mechanics, the communication of moving forces; and of phenomenology, which in Kant's sense – derived from J.H. Lambert, and very different from its later senses in Hegel or HUSSERL – means the laws for distinguishing apparent from real motions. This work is not an essay in empirical physics but rather an exploration of the conceptual framework into which the empirical results of physics must be fitted.

8 The illusions of theoretical reason

In the 'Transcendental Dialectic', Kant argues that the doctrines of traditional metaphysics are illusions arising from the attempt to use the categories of understanding to gain information about objects that are inaccessible to our forms of intuition. What makes such illusions inevitable is the tendency of human reason to seek the unconditioned, that is, to carry a chain of ideas to its assumed completion even when that lies beyond the bounds of sense. For example, understanding may tell us that wholes consist of parts, and sensibility may allow us to find a smaller part for any given whole; but only reason suggests that decomposition into parts must come to an end in something absolutely simple, something we could never perceive by sense. In its practical use, reason may produce ideas of the unconditioned, such as the idea of the universal acceptability of maxims of action, which do not tell us anything misleading about the world because they do not tell us anything about how the world is at all, only how it ought to be; but in its theoretical use reason appears to tell us things about the world that cannot be confirmed by our senses or are even incompatible with the forms of our perception.

This diagnosis of metaphysical error makes good sense of Kant's procedure in the 'Antinomy of Pure Reason', where he presents a series of conflicts between the form and limits of sensibility as structured by the understanding, on the one hand,

and the pretensions of unconditioned reason, on the other. In early sketches of the *Dialectic* (Reflections 4756–60, 1775–7, 17: 698–713) Kant's diagnoses of all the illusions of traditional metaphysics took this form. In the *Critique*, however, Kant singled out some metaphysical beliefs about the self and about God for separate treatment in the 'Paralogisms of Pure Reason' and 'Ideal of Pure Reason'. These sections offer powerful criticisms of traditional metaphysical doctrines, but require a more complex explanation of metaphysical illusion than the single idea of reason's search for the unconditioned.

In the 'Paralogisms', Kant diagnoses the doctrines of 'rational psychology' that the soul is a *substance* which is *simple* and therefore incorruptible, *numerically identical* throughout the experience of any person, and necessarily *distinct* from any external object (this is how he reformulates the Fourth Paralogism in the second edition (B 409)), as a tissue of ungrounded assertions mistaking the logical properties of the *representation* 'I' or the *concept* of the self for the properties of whatever it is in us that actually thinks (A 355/B 409). Kant's criticism of the traditional metaphysics of the soul is convincing, but does not depend on reason's postulation of the unconditioned; instead, Kant's demonstration that these doctrines arise from confusion between properties of a representation and what is represented showed that they were not inevitable illusions by destroying their credibility once and for all.

The four metaphysical disputes that Kant presents in the 'Antinomy of Pure Reason' are often read as straightforward conflicts between reason and sensibility; but Kant characterizes them as disputes engendered by pure reason itself, so a more complex reading is required. In fact, both sides in each dispute – what Kant calls the 'thesis' and 'antithesis' – reflect different forms of reason's demand for something unconditioned, and what conflicts with the limits of sensibility is the assumption that these demands give rise to a genuine dispute at all. Kant again uses the contrast between 'mathematical' and 'dynamical' to divide the four disputes into two groups, and resolves the disputes in two different ways.

In the first antinomy the dispute is between the thesis that the world has a beginning in time and a limit in space and the antithesis that it is infinite in temporal duration and spatial extension (A 426–7/B 454–5). In the second antinomy, the dispute is between the thesis that substances in the world are ultimately composed of simple parts and the antithesis that nothing simple is ever to be found in the world, thus that everything is infinitely divisible (A 434–5/B 462–3). In each case, thesis and antithesis reflect reason's search for the unconditioned, but in two different forms: in the thesis, reason postulates an ultimate *termination* of a series, and in the antithesis, an unconditional *extension* of the series. In these 'mathematical antinomies', however, Kant argues that *neither* side is true, because reason is attempting to apply its demand for something unconditioned to space and time, which are always *indefinite* in extent because they are finite yet always extendible products of our own cognitive activity (A 504–5/B 532–3).

In the two 'dynamical antinomies' Kant's solution is different. In the third antinomy, the thesis is that 'causality in accordance with laws of nature' is not the only kind of causality, but there must also be a 'causality of freedom' underlying the whole series of natural causes and effects, while the antithesis is that everything in nature takes place in accord with deterministic laws alone (A 444–5/B 462–3). In the fourth antinomy, the thesis is that there must be a necessary being as the cause of the whole sequence of contingent beings, either as its first member or underlying it, while the antithesis is that no such being exists inside or outside the world (A 452–3/B 480–1). Again, the theses result from reason's desire for closure and the antitheses result from reason's desire for infinite extension. But now the theses do not necessarily refer solely to spatio-temporal entities, so the claims that there must be a non-natural causality of freedom and a necessary being can apply to things in themselves while the claims that there are only contingent existents linked by laws of nature apply to appearances. In this case both thesis and antithesis may be true (A 531/B 559). This result is crucial to Kant, because it means that although theoretical reason cannot prove that either freedom or God exist, neither can it disprove them, and room is left for the existence of freedom and God to gain credibility in some other way.

The last main part of the 'Dialectic' is Kant's critique of rational theology. Here Kant reiterates his earlier critique of the ontological argument as well as his claim that the arguments for the existence of God from contingency and from design – the 'cosmological' and 'physico-theological' proofs – can only get from their ideas of a first cause or architect to the idea of a *perfect* being by the supposition of the ontological argument, and thus fall along with that. But he now precedes this argument with a critique of the argument for God as the ground of all possibility that he had earlier accepted: the very idea that there is an *ens realissimum*, an individual being containing in itself the ground of 'the sum-total of all possibility' (A 573/B 602), is another of the natural but illusory ideas of reason.

Kant does not, however, conclude the first *Critique* with an entirely negative assessment of

pure reason. In an appendix to the 'Transcendental Dialectic', he argues that even though reason in its theoretical use cannot yield metaphysical insight, it does supply us with indispensable 'regulative' principles, of both the maximal simplicity of natural laws and the maximal variety of natural forms, for the conduct of empirical research; and in the 'Canon of Pure Reason', he argues that practical reason supplies an ideal of the highest good, the union of virtue and happiness and ultimately the union of freedom and nature, which is indispensable for moral conduct, not as its direct object but as a necessary condition of its rationality – which in turn gives ground for the practical postulation if not theoretical proof of the existence of God. Kant expands on both of these ideas in subsequent works (see §11 and §13).

9 The value of autonomy and the foundations of ethics

In his theoretical philosophy, Kant argued that we can be certain of the principles that arise from the combination of the forms of our sensibility and understanding, as products of our own intellectual autonomy; but he also argued that any attempt to see human reason as an autonomous source of metaphysical insight valid beyond the bounds of human sensibility leads to illusion. But in his practical philosophy, Kant argues that human reason is an autonomous source of principles of conduct, immune from the blandishments of sensual inclination in both its determinations of value and its decisions to act, and indeed that human autonomy is the highest value and the limiting condition of all other values.

Traditionally, Kant has been seen as an ethical formalist, according to whom all judgments on the values of ends must be subordinated to the obligatory universality of a moral law derived from the very concept of rationality itself. This interpretation has drawn support from Kant's own characterization of his 'paradoxical' method in the *Critique of Practical Reason*, where he holds that the moral law must be derived prior to any determination of good or evil, rather than vice versa (1900: 5: 62–3). But this passage does not do justice to the larger argument of Kant's practical philosophy, which is that rationality itself is so valuable precisely because it is the means to freedom or autonomy. Kant expressed this in his classroom lectures on ethics, when he said that 'the inherent value of the world, the *summum bonum*, is freedom in accordance with a will which is not necessitated to action' (27: 1482), and even more clearly in lectures on natural right given in the autumn of 1784, the very time he was writing the *Groundwork of the Metaphysics of Morals*, where he said that 'If only rational beings can be ends in themselves, that is not because they have reason, but because they have freedom. Reason is merely a means' (27: 1321). Kant makes the same point in the *Groundwork* when he says that the incomparable dignity of human beings derives from the fact that they are 'free with regard to all laws of nature, obeying only those laws which' they make themselves (4: 435).

The strategy of the *Groundwork* is by no means obvious, and the real character of Kant's view emerges only gradually. In Section I, Kant tries to derive the fundamental principle of morality from an analysis of 'ordinary rational knowledge of morality.' The key steps in his analysis are: virtue lies in the good will of an agent rather than any natural inclination or any particular end to be achieved; good will is manifested in the performance of an action for the sake of fulfilling duty rather than for any other end; and what duty requires is the performance of an action not for the sake of its consequences but because of its conformity to law as such; thus the maxim, or subjective principle, of virtuous action can only be that 'I ought never to act except in such a way *that I can also will that my maxim should become a universal law*' (4: 402). In Section II, Kant apparently tries to reach the same conclusion from more philosophical considerations: by arguing on the one hand that a moral or practical law must be a categorical rather than hypothetical imperative, that is, one commanding unconditionally rather than depending upon the adoption of some antecedent and optional end, and on the other hand that happiness is too indeterminate an end to give rise to such an imperative, Kant concludes that a categorical imperative can contain 'only the necessity that our maxim should conform to this law', thus that 'there remains nothing to which the maxim has to conform except the universality of a law as such' (4: 421). This version of the categorical imperative is known as the Formula of Universal Law.

Kant then furnishes further formulations of the categorical imperative, especially the Formula of Humanity as an End in Itself – '*Act in such a way that you always treat humanity, whether in your own person or in the person of any other, never simply as a means, but always at the same time as an end*' (4: 429), which at the very least requires the possibility of rational consent to your action from any agent affected by it – and the formula of the kingdom of ends, the requirement that any proposed course of action be compatible with 'a whole of all ends in systematic conjunction (a whole both of rational beings as ends in themselves and also of the personal ends which each may set before himself' (4: 433). The usual interpretation is that these two formulations are

supposed to follow from the Formula of Universal Law. However, several factors suggest that Kant did not mean the derivation of that formula from either common sense or 'popular moral philosophy' to be self-sufficient, and it is only with the introduction of the notion that humanity is an end in itself because of its potential for freedom, that the real 'ground of a possible categorical imperative' is discovered (4: 428). If so, then this is Kant's theory: the ultimate source of value is human freedom as an end in itself, manifested in interpersonal contexts in the possibility of freely given consent to the actions of others; conformity to the requirement of universal law is the way to ensure that this value is preserved and fostered; and the ideal outcome of the observation of such a law would be a kingdom of ends as a system of freedom, in which all agents freely pursue their freely chosen ends to the extent compatible with a like freedom for all.

10 Duties of right and duties of virtue

In the *Groundwork*, Kant's principle of morality gives rise to a fourfold classification of duties, resulting from the intersection of two divisions: between duties to oneself and to others, and between perfect and imperfect duties. Perfect duties are proscriptions of specific kinds of actions, and violating them is morally blameworthy; imperfect duties are prescriptions of general ends, and fulfilling them by means of performing appropriate particular actions is praiseworthy. The four classes of duty are thus: perfect duties to oneself, such as the prohibition of suicide; perfect duties to others, such as the prohibition of deceitful promises; imperfect duties to oneself, such as the prescription to cultivate one's talents; and imperfect duties to others, such as the prescription of benevolence (1900: 4: 422–3, 429–30). It is straightforward what a perfect duty prohibits one from doing; it requires judgment to determine when and how the general ends prescribed by imperfect duties should be realized through particular actions.

In the later *Metaphysics of Morals*, Kant works out a detailed budget of duties that is generally based on this scheme, but with one key distinction: duties of justice (*Recht*) are those of the above duties that can appropriately be enforced by means of the public, juridical use of coercion, and the remainder are duties of virtue, which are fit subjects for moral assessment but not coercion (6: 213, 219). Since freedom is Kant's chief value, coercion is permitted only where it is both necessary to preserve freedom and possible for it to do so. This means that only a small subset of our duties, namely some but not all of our perfect duties to others, are duties of justice, thus proper subjects for public legislation; the majority of our moral duties are duties of virtue which are not appropriate subjects for coercive legal enforcement.

Kant's treatment of the duties of virtue is less complicated than that of the duties of justice, and will be considered first. Kant does not explicitly characterize these as duties to preserve and promote the freedom of oneself and others, as he does in the *Groundwork*, but instead characterizes them as duties to promote one's own perfection and the happiness of others: while one can directly perfect one's own freedom, one can avoid injuring but not directly perfect the freedom of another. On close inspection, however, Kant's duties of virtue require precisely that one perfect both the internal and external conditions for the exercise of one's own freedom and at least the external conditions for the exercise of the freedom of others. Thus, ethical duties to oneself include the prohibition of injury to the physical and mental bases of one's free agency, as by suicide or drunkenness, and the prescription of efforts to improve both the physical and mental conditions for the exercise of one's freedom, as by the cultivation of talents and of one's spiritual and moral faculties themselves; and ethical duties to others include both the prohibition of injuries to the dignity of others as free agents, for example by insulting or ridiculing them ('duties of respect'), and the prescription of efforts to improve the conditions for others' exercise of their own freedom, as by beneficience and sympathy ('duties of love').

Kant's foundation of his political philosophy on the duties of justice is more complicated. From the ultimate value of freedom, Kant derives the universal principle of justice, that an action is right only if 'on its maxim the freedom of choice of each can coexist with everyone's freedom in accordance with a universal law' (6: 230). Kant then argues that coercion is justified when it can prevent a hindrance to freedom, since a hindrance to a hindrance to freedom is itself a means to freedom (6: 231). This is too simple, since coercion might only compound the injury to freedom. Kant needs to add that coercive enforcement of the law is not itself a hindrance to freedom, since the threat of juridical sanction does not deprive a would-be criminal of freedom in the way that his crime would deprive its victim of freedom: the criminal exercises the choice to risk sanction, but deprives his victim of a like freedom of choice.

Kant goes on to argue that the only proper aim of coercive juridical legislation is the prevention of injury to the person and property of others; this is 'Private Law', while 'Public Law' concerns the proper form of the state, whose function is the enforcement of private law. Kant takes the prevention of injury to persons to be an obvious

requirement of duty, needing no special discussion, but the right to property receives extended discussion.

Kant recognizes three classes of property: property in things, property in contracts, and contract-like property in other persons, such as marital rights. His discussion of property in things is the most important for his political theory. The gist of Kant's account is that it would be irrational to deprive ourselves of the right to place physical objects, above all land, at our own long-term disposal, since we are rational agents who may need to use such things to realize our freely chosen ends, while the things themselves are not free agents and have no rights. But since the earth is initially undivided, specific property rights are not innate but must be acquired. Since the claim to any particular thing would limit the freedom of others who might also be able to use it, however, property rights cannot be claimed unilaterally, at least if morality's insistence upon universal acceptability is to be respected, but can only be claimed with the multilateral consent of those others, which they can reasonably give only if they too are accorded similar rights necessary for the successful exercise of their own agency (6: 255–6). For Kant, the right to property is thus not a natural right of isolated individuals, but a social creation depending upon mutual acceptability of claims. The state, finally, exists primarily to make claims to property rights both determinate and secure, and anyone claiming property rights thus has both the right and the obligation to join in a state with others (6: 256–7, 306–8). Since property exists only by mutual consent, and the state exists to secure that consent, the state necessarily has the power to permit only those distributions of property rights sufficiently equitable to gain general consent.

Both claims to property and expressions of philosophical and religious opinions, for example, are expressions of human autonomy. But while one person's property claims may directly limit the freedom of others, and are therefore subject to public regulation, his beliefs do not, and thus do not require the consent of any other. The state therefore has no right to intervene in these matters. This fundamental difference between the state's proper concern with property and its improper concern with personal belief defines Kant's liberalism. It is only implicit in the *Metaphysics of Morals*, but becomes explicit in more purely political writings.

11 Freedom of the will and the highest good

Having considered some practical implications of Kant's conception of autonomy, we now turn to its metaphysical consequences.

In Section III of the *Groundwork*, Kant attempts to prove that the categorical imperative, derived in Section II by the analysis of the concept of free and rational beings in general, actually puts *us* under an obligation by proving that *we* are indeed free and rational beings. In his terminology, he wants to show that it is not merely an analytic but a synthetic a priori proposition that our wills are constrained by this imperative. Both the interpretation and the assessment of the arguments by which he proposes to accomplish this remain controversial.

The first claim that Kant makes is that 'every being who cannot act except under the idea of freedom is just on that account really free in a practical respect, that is, all laws that are inseparably bound up with freedom are valid for it just as if its will were really declared to be free in itself and in theoretical philosophy', and that every being with a will must indeed act under the idea of freedom (1900: 4: 448) (see Will, the). This seems to mean that agents who conceive of themselves as choosing their own actions, whether or not they conceive of themselves as subject to determinism, do not or perhaps even cannot consider any antecedent determinants of their actions in deciding what to do, but only what now seems most rational to do; thus they must govern their actions by rational and therefore moral laws. This seems right for agents considering their own future actions, but leaves unclear how we are to assess the freedom of the actions of others or even our own past actions.

However, Kant goes on to offer what seems to be a theoretical and therefore general proof of the existence of human freedom. He argues that theoretical philosophy has shown that we must distinguish between considering ourselves as phenomena and noumena, or members of the sensible and the intelligible worlds. From the first point of view, we must consider our actions to be governed by the causality of nature, while in the second, since we cannot consider our actions there to be governed by no law at all, we must consider them to be governed by another kind of causality, namely causality in accord with laws of reason (4: 451–3). Thus while our actions appear to be determined by natural causes, in reality they not only can but in fact must accord with laws of reason, hence with the categorical imperative.

There are two problems with this argument. First, it flouts transcendental idealism by assuming positive knowledge about things in themselves. Second, as Henry Sidgwick was to object a century later, it precludes moral responsibility for wrong-doing: if the real laws of our behaviour are necessarily rational and hence moral, any wrong-doing could only show that an agent is not rational, and therefore not responsible, at all.

Whether consciously aware of such objections or not, Kant began to alter his argument for freedom of the will in the *Critique of Practical Reason*. Here he does not argue from a theoretical proof of our freedom to the fact of our obligation under the moral law, but conversely from our consciousness of that obligation – the 'fact of reason' – to our freedom as the necessary condition of our ability and responsibility to fulfil it (5: 29–31). This argument first assumes that transcendental idealism has left open at least the theoretical possibility of freedom of the will, and then depends upon the famous principle 'ought implies can' ('Theory and Practice', 8: 287). Transcendental idealism, of course, seems problematic to many; and although the 'ought implies can' principle seems an intuitive principle of fairness, Kant does not actually argue for it. Nevertheless, since this argument assumes only that 'ought' implies '*can*', it does not imply that any agent who is obliged under the moral law necessarily *will* act in accordance with it, and thus avoids Sidgwick's problem about the very possibility of wrong-doing.

Kant depends upon this result in his next major treatment of freedom, in *Religion within the Limits of Reason Alone*, although there he seems to go too far in the other direction by assuming that evil-doing is not just possible but even necessary. Kant begins this discussion with an elegant account of wrong-doing, arguing that because no human being is simply unaware of the demand of morality – that is implied by the 'fact of reason' – acting immorally never comes from mere ignorance of the moral law, but rather from deciding to exempt oneself from this obligation. This position is compatible with the argument for freedom in the second *Critique*, although not with that of the *Groundwork*. However, Kant goes on to argue that an evil rather than virtuous choice of fundamental maxim, or 'radical evil', is not only *possible* but inevitable, to be escaped from only by a moral conversion. This doctrine hardly follows from Kant's previous argument, and seems instead to rest on an odd mixture of empirical evidence and the lingering grip of the Christian doctrine of original sin.

The reality of freedom is only the first of Kant's three 'postulates of pure practical reason'; the other two are the existence of God and the immortality of the soul. Again Kant's argument is that, as the first *Critique* showed, neither of these can be proven by theoretical metaphysics, but they can nevertheless be postulated as necessary conditions of something essential to morality. In this case, however, they are conditions not of our obligation under the categorical imperative but for the realization of the 'highest good'. This is another complex and controversial concept. Kant typically defines it as happiness in proportion to virtue, which is worthiness to be happy (5: 110), but suggests different grounds for the necessity of this conjunction. In the *Critique of Practical Reason*, Kant sometimes treats happiness and virtue as two separate ends of human beings, one our natural end and the other our moral end, which we simply seek to combine (5: 110). In other places, however, beginning with the 'Canon of Pure Reason' in the first *Critique*, he holds that since what virtue does is precisely to coordinate our mutual pursuit of ends, and happiness arises from the realization of ends, maximal happiness would inevitably follow maximal virtue under ideal circumstances (A 809/B 837). Of course, circumstances are not always ideal for morality: as far as we can see, no one achieves perfect virtue in a normal lifespan, and such virtue as is attained is hardly always rewarded with happiness. To counter this, Kant holds that we may postulate immortality, in which to perfect our virtue, and the existence of God, who can legislate a nature in which the ends of virtue are achieved.

This theory has seemed to many to be Kant's vain attempt to save his personal faith from his own scathing critique of metaphysics. Before such a claim could even be discussed, we would have to know what Kant really means by a postulate of practical reason. Kant gives several hints about this which have not been adequately explored. In the first *Critique*, he discusses the practical postulates in a section where he considers readiness to bet as a measure of belief, thus suggesting that what he actually has in mind is Pascal's wager (see PASCAL, B.): since there is no theoretical disproof of these postulates, and nothing to lose if they are false, but their value to happiness is great, it is rational to act as if they were true. In a later essay, a draft on the 'Real Progress of Metaphysics from the Time of Leibniz and Wolff' from the early 1790s (posthumously published), Kant makes an even more striking suggestion. There he says that in the assumption of the practical postulates 'the human being is authorized to grant influence on his actions to an idea which he, in accord with moral principles, has made himself, just as if he had derived it from a given object' (20: 305). Here the suggestion is that the practical postulates are nothing less than another expression of human autonomy: not theoretical beliefs at all, let alone religious dogmas, but ideas which we construct for ourselves solely to increase our own efforts at virtue. This idea, that God is in fact nothing but an idea of our own making for use within our moral practice, is a thought Kant repeatedly expressed in his very last years (see §14).

12 Taste and autonomy

Under the rubric of 'reflective judgment', defined as that use of judgment in which we seek to find

unknown universals for given particulars rather than to apply given universals to particulars (5: 179–80), the *Critique of the Power of Judgment* deals with three apparently disparate subjects: systematicity in scientific concepts generally, natural and artistic beauty, and teleology or purposiveness in particular organisms and in nature as a whole (see TELEOLOGY). Even more than the idea of reflective judgment, however, what ties these subjects together is again the idea of autonomy.

In the the first *Critique*, Kant had suggested, with but few exceptions, that the search for systematicity in scientific concepts and laws – the subordination of maximally varied specific concepts and laws under maximally unified general ones – is an ideal of reason, not necessary for empirical knowledge but still intrinsically desirable. In the third *Critique*, he reassigns this search to reflective judgment, and argues that we must adopt as a transcendental but indemonstrable principle that nature is adapted to our cognitive needs (5: 185; 20: 209–10). By this reassignment Kant indicates that systematicity is a necessary condition for the acceptance of empirical laws after all, and thus a necessary condition for experience itself. Kant thereby suggests that our empirical knowledge is neither passively received nor simply guaranteed, but dependent on our active projection of the unity of nature.

Kant next turns to judgments of taste as both a further expression of human autonomy and further evidence that the adaptation of nature to our own cognitive needs is both contingent yet reasonably assumed. Judgments of taste, beginning with the simplest such as 'This flower is beautiful' and progressing to more complex ones such as 'This poem is beautiful' and 'This landscape is sublime', are connected to autonomy in two ways: while they claim universal agreement, they must always be based on individual feeling and judgment; and while they must be made free of all constraint by theoretical or moral concepts, they are ultimately symbols of moral freedom itself.

Kant begins from an analysis of the very idea of an 'aesthetic judgment'. As aesthetic, judgments of taste must both concern and be made on the basis of the most subjective of human responses, feelings of pleasure, but, as judgments, they must still claim interpersonal agreement (5: 203, 212–16). To retain their link to feelings, judgments of taste can never simply report how others respond, but must be based on one's own free response to the object itself; in this way they express individual autonomy (5: 216, 282–5). But to claim universal agreement, they must be based on cognitive capacities shared by all, yet by a condition of those faculties that is pleasurable because it is not constrained by rules (5: 187). Such a state is one of 'free play' between imagination and understanding, in which the imagination satisfies understanding's need for unity by presenting a form that seems unitary and coherent without any concept, or, even where a concept of human use or artistic intention is inescapable, that seems to have a unity going beyond any such concept – artistic genius lies precisely in such transcendence of concepts (5: 317–18). With debatable success, Kant argues that this 'free play' must occur under the same circumstances in all human beings (5: 238–9, 290), and thus that judgments of taste can have the 'quantity' of universality and the 'modality' of necessity while retaining the 'quality' of independence from direct moral interest and 'relation' to merely subjective, cognitive interests rather than objective, practical ones.

How does aesthetic judgment so understood both express autonomy in a moral sense and also give further evidence of the contingent adaptation of nature to our own needs? Kant answers the latter question with his idea of 'intellectual interest': the very fact that beauty exists, he argues, although it cannot be derived from any scientific laws, can be taken by us as evidence that nature is receptive not only to our cognitive needs but even to our need to see a possibility for success in our moral undertakings (5: 300). Kant's answer to the first question, how taste expresses autonomy in its moral sense, is more complex but also more compelling than this.

Like other eighteenth-century authors such as Edmund BURKE, Kant draws a fundamental distinction between the beautiful and the sublime (see SUBLIME, THE). Beauty pleases us through the free play of imagination and understanding. In our response to the sublime, however – which for Kant is not paradigmatically a response to art, but to the vastness and power of nature – we enjoy not a direct harmony between imagination and understanding, which are rather frustrated by their inability to grasp such immensities, but a feeling of them which reveals the power of reason within us (5: 257). And this, although it would seem to involve theoretical reason, symbolizes the power of practical reason, and thus the foundation of our autonomy, in two ways: our power to grasp a truly universal law, such as the moral law, and our power to resist the threats of mere nature, and thus the blandishments of inclination (5: 261–2).

In this way, the sublime symbolizes the sterner side of moral autonomy. But the experience of beauty is also a symbol of morality, precisely because the freedom of the imagination that is its essence is the only experience in which any form of freedom, including the freedom of the will itself, can become palpable to us (5: 353–4). Kant thus concludes his critique of aesthetic judgment with the remarkable suggestion that it is in our enjoyment of beauty that

our vocation as autonomous agents becomes not just a 'fact of reason' but a matter of experience as well.

13 Design and autonomy

Kant's critique of teleological judgment in the second half of the *Critique of Judgment* has an even more complicated agenda than his aesthetic theory. The work has roots in both eighteenth-century biology – which began the debate, lasting until the twentieth century, whether organisms could be understood on purely mechanical principles – and natural theology – that is, the great debate over the argument from design that culminated in Hume's *Dialogues concerning Natural Religion*. Yet again Kant's motive is to show that even our understanding of nature ultimately drives us to a recognition of our own autonomy.

The work is divided into three main sections: an examination of the necessary conditions for our comprehension of individual organisms; an examination of the conditions under which we can see nature as a whole as a single system; and a restatement of Kant's moral theology. First, Kant argues that an organism is a system of whole and parts manifesting both 'regressive' and 'progressive' causality: the whole is the product of the parts, but the parts in turn depend upon the whole for their own proper functioning and existence (1900: 5: 372, 376). But our conception of mechanical efficient causation includes only progressive causation, in which the state of any system depends upon the prior state of its parts (see CAUSATION). The only way we can understand the regressive causation of the whole with respect to its parts is by analogy to intelligent design, in which an antecedent *conception* of the object as a whole determines the production of the parts which in turn determine the character of the resultant whole. However, Kant insists, we have absolutely no justification for adopting a 'constitutive concept' of natural organisms as a product of actual design; we are only entitled to use an analogy between natural organisms and products of design as 'a regulative concept for reflective judgment to conduct research into objects in a remote analogy with our own causality in accordance with purposes' (5: 375). In other words, seeing organisms as products of intelligent design is a purely heuristic strategy.

However, Kant next argues that if it is natural for us to investigate organisms as if they were products of intelligent design, then it will also be natural for us to try to see nature as a whole as manifesting a purposive design (5: 380–1); and only by seeing the whole of nature as a product of intelligent design – of course, only regulatively – can we satisfy our craving to transform every particularity of nature, which must always be left contingent by our own general concepts, into something that seems necessary (5: 405–7). However, from a merely naturalistic viewpoint the ultimate purpose of nature as a system must remain indeterminate – grass might exist to feed cows, or cows exist to fertilize the grass (4: 426). Nature can be seen as a determinate system only if it can be seen as collectively serving an ultimate end that is itself an intrinsic end, that is, an end with absolute value. This can only be humanity itself (4: 427) – but not humanity merely as a part of nature, seeking happiness, which is neither a determinate end nor one particularly favoured by nature (4: 430), but only humanity as the subject of morality, able to cultivate its freedom (5: 435–6). Thus the urge to see nature as a systematic whole, an inevitable concomitant of our research into the complexities of organic life, can only be satisfied from the moral point of view in which human autonomy is the ultimate value.

Kant is still careful to remind us that this doctrine is regulative, furnishing us with a principle for our own cognitive and practical activity, not constitutive, pretending to metaphysical insight into the nature of reality independent from us. It is therefore particularly noteworthy that the last part of the critique of teleological judgment is a restatement of Kant's moral theology, the argument for belief in the existence of God as a postulate of practical reason. This restatement within a general theory of reflective judgment, the principles of which are meant above all else to guide our own activity, confirms the view that in the end the theory of practical postulates is not meant to support any form of dogma but only to serve as another expression of our own autonomy.

14 The final decade of Kant's public and private career

German intellectuals were drawn to political issues after the French revolution in 1789, and Kant was no exception. Key elements of his political philosophy were presented in essays such as 'Theory and Practice' (1793) and *Perpetual Peace* (1795) before its formal exposition in the *Metaphysics of Morals* (1797). As was argued above (§10), the foundation of Kantian liberalism is the idea that coercion is justifiable only to prevent hindrances to freedom, and thus to protect personal freedom and regulate property, every claim to which represents a potential constraint of the freedom of others unless they can reasonably agree to that claim as part of a system of property rights; but individual beliefs and conceptions of the good, whether religious or philosophical, do not directly interfere with the freedom of others and are therefore not a proper object of political

regulation. Kant's development of this basic principle into a political philosophy, however, is complex and controversial.

On the one hand, Kant argued from this premise to a firm rejection of any paternalistic government, even benevolent paternalism. Government exists for the protection of the freedom individuals have to determine and pursue their own ends to the extent compatible with the like freedom of others; so a '*paternalistic government*, where the subjects, as minors, cannot decide what is truly beneficial or detrimental to them, but are obliged to wait passively for the head of state to judge how they *ought* to be happy... would be the greatest conceivable *despotism*' (1900: 8: 290–1). Further, Kant held that the sovereignty of any government derives solely from the possibility of those who are governed rationally consenting to it, and thus that it is a necessary test of the legitimacy of all laws 'that they can have arisen from the united will of an entire people' (8: 297). These constraints could best be met in a republic, without a hereditary monarchy or aristocracy pitting proprietary privilege against public right. Finally, Kant argued in *Perpetual Peace*, only in a world federation of republics, where no proprietary rulers could identify the forcible extension of their domains with the aggrandizement of their personal property, could a cessation of warfare ever be expected.

On the other hand, Kant accompanied these liberal doctrines with a denial of any right to violent revolution, which has seemed surprising to many. But Kant's thought here is complex. Underlying his position as a whole is his view that in any situation in which different persons are bound to come into contact with each other we have not merely a moral right but a moral obligation to found or uphold a state. But one could easily argue that a tyranny is a state in name only, and that our moral obligation with regard to a tyranny is precisely to replace it at any cost with a legitimate state. Kant offers several reasons why this is not so. One claim is that violent revolution does not leave time for genuine reform in principles (8: 36), and another argument is that people revolt for the sake of greater happiness, which is an illegitimate reason for the overthrow of a state (8: 298). But these are empirical claims, and do not prove that people cannot revolt solely to remove illegitimate constraints to their freedom. Another argument Kant makes is that a constitution granting a legal right to rebel against the highest authority it creates would thereby not create a single highest authority after all, and would thus be self-contradictory (6: 319). This has seemed to many to be a sophism; but it may have been Kant's attempt to get his liberalism past the Prussian censorship, denying a *legal* right to rebel without ever explicitly denying a *moral* right to rebel.

Kant had been battling censorship even before the death of Frederick the Great in 1786. In 'What is Enlightenment?' (1785), he argued that while persons in an official capacity have to obey orders (in what he confusingly calls the 'private use of reason'), no official, not a professor or even a military officer, has to surrender his right to address his views to 'the entire *reading public*' (the 'public use of reason') (8: 37). But Kant's attack on the necessity of an established church in *Religion within the Limits of Reason Alone* (1793), even though legally published with the imprimatur of a non-Prussian university (Jena), outraged the conservative Frederick William II and his minister Wöllner, and Kant was threatened with punishment if he published further on religion. With an oath of loyalty to his sovereign, Kant promised to desist, but after the death of this king in 1797 he regarded himself as freed from this promise, and the next year issued his most spirited defence of intellectual freedom yet, *The Conflict of the Faculties*. Here Kant argued that while the theological faculty might have the obligation to advance certain dogmas approved by the state, it was nothing less than the official function of the philosophical faculty to subject all views to rational scrutiny; and in any case, a government genuinely concerned with its people's welfare would not want them to base their morality on fear or dogma but only on the free exercise of their own reason. The new government had no stomach for further suppression of the aged philosopher, and Kant was able to publish this defence of intellectual freedom without incident.

Privately, Kant's last years were devoted to the project of closing the gap between the metaphysical foundations of natural science and actual physics, begun about 1796. He never published the work, leaving behind only the notes later published as the *Opus postumum*. Here Kant tried to show that by using the categorial framework and the concept of force we can derive not only the most general laws of mechanics, as he had argued in 1786, but a much more detailed categorization of the forms of matter and its forces. Kant also argued that an imperceptible, self-moving ether or 'caloric' is a condition of the possibility of experience. In the latest stages of this work, however, Kant returned to the broadest themes of his philosophy, and tried to develop a final statement of transcendental idealism. Here he argued that 'The highest standpoint of transcendental philosophy is that which unites God and the world synthetically, under one principle' (21: 23) – where that principle is nothing other than human autonomy itself. God and the world are 'not substances outside my thought, but rather the thought through which we ourselves make these objects' (21: 21): the world is our experience

organized by categories and laws of our own making, and God is the representation of our own capacity to give ourselves the moral law through reason. The moral law 'emerges from freedom . . . - which the subject prescribes to himself, and yet as if another and higher person had made it a rule for him. The subject feels himself necessitated through his own reason...' (22: 129). This is a fitting conclusion to Kant's philosophy of autonomy.

KANTIAN ETHICS

Introduction

Kantian ethics originates in the ethical writings of Immanuel Kant (1724–1804), which remain the most influential attempt to vindicate universal ethical principles that respect the dignity and equality of human beings without presupposing theological claims or a metaphysical conception of the good. Kant's systematic, critical philosophy centres on an account of reasoning about action, which he uses to justify principles of duty and virtue, a liberal and republican conception of justice with cosmopolitan scope, and an account of the relationship between morality and hope.

Numerous contemporary writers also advance views of ethics which they, and their critics, think of as Kantian. However, some contemporary work is remote from Kant's philosophy on fundamental matters such as human freedom and reasoning about action. It converges with Kant's ethics in claiming that we lack a substantive account of the good (so that teleological or consequentialist ethics are impossible), in taking a strong view of the equality of moral agents and the importance of universal principles of duty which spell out what it is to respect them, and in stressing an account of justice and rights with cosmopolitan scope.

Both Kant's ethics and contemporary Kantian ethics have been widely criticized for preoccupation with rules and duties, and for lack of concern with virtues, happiness or personal relationships. However, these criticisms may apply more to recent Kantian ethics than to Kant's own ethics.

1 Kant's ethics

Kant's main writing on ethics and politics can be found in *Grundlegung zur Metaphysik der Sitten* (*Groundwork of the Metaphysics of Morals*) (1785), *Kritik der practischen Vernunft* (*Critique of Practical Reason*) (1788), *Die Metaphysik der Sitten* (*The Metaphysics of Morals*) (1797) and numerous sections of other works and free-standing essays. Throughout these writings he insists that we cannot derive ethical conclusions from metaphysical or theological knowledge of the good (which we lack) or from a claim that human happiness is the sole good (which we cannot establish). We lack the basis for a teleological or consequentialist account of ethical reasoning, which therefore cannot be simply a matter of means-ends reasoning towards some fixed and knowable good (see CONSEQUENTIALISM; TELEOLOGICAL ETHICS).

Yet if reasoning about action, that is practical reasoning, is not means-end reasoning, what can it

be? Kant's alternative account proposes simply that reasons for action must be reasons for all. He insists that we can have reasons for recommending only those principles of action which could be adopted by all concerned, whatever their particular desires, social identities, roles or relationships. Correspondingly, practical reasoning must reject any principles which cannot be principles for all concerned, which Kant characterizes as *non-universalizable* principles (see UNIVERSALISM IN ETHICS).

Kant gives this rather limited modal conception of practical reasoning some grand names. He calls it the 'supreme principle of morality' and the 'categorical imperative'. He formulates this fundamental principle of ethics in various ways. The formulation most discussed in the philosophical literature runs 'act only on that maxim [principle] through which you can at the same time will that it become a universal law'. The formulation that has had and still has the greatest cultural resonance requires us to treat others with impartial respect. It runs 'treat humanity . . . never simply as a means, but always at the same time as an end' ([*Grundlegung* 1785). The equivalence of these two formulations of the categorical imperative is far from obvious. One way of glimpsing why Kant thought they were equivalent is to note that if we treat others as persons rather than as things then we must not destroy or impair their abilities to act, indeed must leave it open to them to act on the same principles that we act on; hence we must act on universalizable principles. On Kant's view, one of the worst features of consequentialist ethics is that it not merely permits but requires that persons be used as mere means if this will produce good results.

Kant claims that the categorical imperative can be used to justify the underlying principles of human duties. For example, we can show by a *reductio ad absurdum* argument that promising falsely is not universalizable. Suppose that everyone were to adopt the principle of promising falsely: since there would then be much false promising, trust would be destroyed and many would find that they could not get their false promises accepted, contrary to the hypothesis of universal adoption of the principle of false promising. A maxim of promising falsely is not universalizable, so the categorical imperative requires us to reject it. Parallel arguments can be used to show that principles such as those of coercing or doing violence are not universalizable, and so that it is a duty to reject these principles.

Kant calls duties such as these *perfect* (namely, complete) duties. These are duties which can observed by each towards all others. He also provides arguments to establish the principles of certain *imperfect* (namely, incomplete) duties, such as those of helping others in need or developing one's own talents. One way in which imperfect duties are unavoidably incomplete is that they cannot be observed towards all others: nobody can help all others, or develop all possible talents. Kant calls these imperfect duties 'duties of virtue' (see VIRTUES AND VICES §§2–3).

The derivation of principles of duty from his conception of practical reason is the core of Kant's ethics, and provides the context for his discussion of many other themes. These include: the difference between internalizing principles and merely conforming to them in outward respects ('acting out of duty' versus 'acting according to duty'); the place of happiness in a good life; the need for judgment in moving from principle to act (see MORAL JUDGMENT §2); the justification of state power; and the justification of a cosmopolitan account of justice. He also develops the connections between his distinctive conceptions of practical reason and of freedom and his equally distinctive view of religion, which he sees as a matter not of knowledge but of reasoned hope for a future in which morality can be fully realized. In some works Kant articulates reasoned hope in religious terms; in others he articulates it in political and historical terms as a hope for a better this-worldly human future.

2 Contemporary Kantian ethics

Much contemporary work on ethics is labelled Kantian, in the main because it does not derive an account of right action from one of good results, but rather sees the right as prior to the good (RIGHT AND GOOD). In contemporary Kantian work obligations and rights are the fundamental ethical notions. Such work is often called *deontological ethics* (the term derives from the Greek word for *ought*) (see DEONTOLOGICAL ETHICS). Deontological ethical theories are contrasted with teleological or consequentialist theories, which treat the good as prior to the right. Deontological theories are concerned with ethically required action, hence with principles, rules or norms, with obligations, prohibitions and permissions, and with justice and injustice, but not with virtues, good lives, moral ideals and personal relationships.

Deontological ethics has many distinct forms. Many versions endorse one or another interpretation of the Kantian demand to respect persons, and think that moral principles should be universal; few mention Kant's minimalist strategy for justifying certain universally binding principles as those we must live by if we reject non-universalizable principles. Indeed, many deontological ethical theories rely on conceptions of freedom, reason and action which are unlike Kant's, and resemble those typically used by consequentialists.

One prominent range of deontological positions seeks to justify principles of justice by showing that they would be agreed to by all concerned under certain hypothetical conditions. They draw on the thought that agreements and contracts are good reasons for action, and suggest that all ethical claims are to be justified by showing that they are based if not on actual then on hypothetical agreements or contracts. These sorts of deontological theories are often called *contractarian* or *contractualist*; they are contemporary versions of social contract theories (see CONTRACTARIANISM).

Some contractualists take a Hobbesian rather than a Kantian approach. They argue that principles of justice are those on which instrumentally rational persons, guided by their individual preferences, would agree (see HOBBES, T. §§6–7). Other contractualists take a more Kantian approach. They argue that principles of justice are those which would be accepted or agreed to by persons who are not merely instrumentally rational but can use certain reasonable procedures.

The best known exponent of Kantian contractualism is John RAWLS, whose *A Theory of Justice* (1971) identifies principles of justice as those that would be agreed by rational and self-interested beings in circumstances which ensure that their choosing will be reasonable as well as rational. He argues that principles of justice would emerge if they were chosen by all concerned in an hypothetical situation devised to ensure impartiality and hence agreement. Rawls calls this hypothetical situation 'the original position', and represents it as one in which persons are ignorant of their own social position and personal attributes, hence of their own advantage, hence cannot but be impartial.

Rawls claims that rational persons in this hypothetical situation would choose principles of justice that prescribe equal rights for all and the highest attainable level of wellbeing for the worst off. Since everything that differentiates individuals, and could thus provide a basis for disagreement, for bargaining, or for a need to seek agreement, is carefully excluded from the original position, it is not obvious why principles chosen in it should be thought of as matters of *agreement*, or why the parties to the original position should be thought of as *contracting* with one another. Nor is it clear why the fact that certain principles would be agreed to under these conditions justifies those principles to those in other situations. Why are principles which would be agreed to under conditions that do not obtain binding under conditions that actually obtain?

In *A Theory of Justice* Rawls argues that principles that would be so agreed are binding in other situations because they cohere, or form a 'reflective equilibrium' with 'our considered judgments' (see MORAL JUSTIFICATION §2). Principles are justified not merely because the instrumental reasoning of the hypothetically ignorant would select them, but because we would reasonably judge them congruent with our most carefully considered moral views. In his later *Political Liberalism* (1993) Rawls depicts these principles as the outcome not of hypothetical agreement in an original position, but as the hypothetical agreement of persons who are not only rational but reasonable, in the sense that they are willing to abide by principles given assurance that others will do so too. Principles and institutions are just if they are the focus of reasonable agreement by all concerned.

Jürgen HABERMAS has also advocated versions of Kantian ethics which stress agreement between agents. In earlier work he argued that the test of justification or legitimation is that a proposal would be agreed in a hypothetical 'ideal speech situation', in which communication was undistorted. In more recent work (1993), he has argued that legitimation of norms is achieved through processes of public discourse, to which each can contribute and in which all can agree.

3 Criticisms of Kantian ethics

Both Kant's ethics and contemporary Kantian ethics have been criticized from many quarters. The critics evidently include those who advocate one or another form of teleological or consequentialist theory, who believe that it is possible to establish an account of the good, from which a convincing account of the right, and specifically of justice, can be derived. However, they also include a variety of writers who reject consequentialist thinking, including communitarians, virtue ethicists, Wittgensteinians and feminist thinkers (see COMMUNITY AND COMMUNITARIANISM; VIRTUE ETHICS).

The most common and general criticisms are that, because it concentrates on principles or rules, Kantian ethics is doomed to be either empty and formalistic or rigidly uniform in its prescriptions (the complaints cannot both be true). The charge of empty formalism is based on the correct observation that principles underdetermine action; it is usually countered with the equally correct observation that quite indeterminate principles (such as 'Stay within the budget' or 'All religions are to be tolerated') may set significant constraints on action, so are not empty. The charge of rigidly uniform prescriptivity is based on the thought that rules prescribe, so must regiment. It is usually countered by the reminder that since rules can be indeterminate, they need not regiment: universal principles need not be uniformly prescriptive. An ethical theory that applies to

principles can be more than empty and less than rigid.

Other critics, for example MacIntyre, object that since Kantian ethics focuses on obligations and rights, and in good measure on justice, it either must or does neglect other ethical categories, and in particular the virtues, good character or good lives; that 'natural and human rights . . . are fictions' (MacIntyre in, *After Virtue* 1981: 67); and that obligations inevitably conflict in ways that render all deontological ethics incoherent. Some critics have laid particular stress on the point that in requiring impartial respect for all, Kantian ethics wholly ignores the place of happiness, of the emotions, of personal integrity and above all of personal relationships in the good life (see MORALITY AND EMOTIONS). They have claimed that we must choose between an ethics of justice and one of care, an ethic of rules and one of relationships, an ethic of duty and one of virtue, and that the latter term of each pair is to be preferred.

4 Back to Kant?

Some of these criticisms are accurately aimed at significant features of various forms of contemporary Kantian writing in ethics; many of them are less apt as criticisms of Kant's ethics. Several recent writers have suggested that Kant's ethics is the most convincing form of Kantian ethics, and that its distinctive features are strengths rather than weaknesses. Many of these writers accept much of the critique of deontological ethics, but think that not all the criticisms apply to Kant's ethics, of which they offer detailed interpretations. Part of their effort has gone into work on Kant's conceptions of action, reason and freedom, and part into work on his ethics. They have pointed out that Kant's account of practical reason and of its vindication does not assume either that all reasoning about action is instrumentally rational pursuit of preferred ends, or that ethical vindication is located in hypothetical agreements or contracts reached by reasonable procedures. They have stressed that Kant's conception of practical reason is based on universalizability rather than impartiality or reciprocity and that he views obligations rather than rights as basic to ethics. They have insisted that impartial respect for persons and a cosmopolitan approach to justice are not morally negligible matters, and have criticized communitarians, virtue ethicists and some feminist thinkers for not taking justice seriously. They have also pointed out that Kant offers accounts of the virtues, of the role of happiness in the good life, and of judgment, and argued that his position is not damagingly individualistic and that he acknowledges the importance of institutions and of social and personal relationships in human life (see Korsgaard 1996).

KATHARSIS

One of the central concepts of Aristotle's *Poetics*, *katharsis* ('purgation' or 'purification'; often spelled *catharsis*) defines the goal of the tragic poet: the depiction of human vicissitudes so to provoke the spectators' feelings of pity and fear that such emotions in them are finally purged.

GLENN W. MOST

KELSEN, HANS (1881–1973)

Hans Kelsen was one of the foremost (positivist) legal theorists of the twentieth century. He taught in Vienna, Cologne, Geneva and Paris, and finished his life in America, teaching in Chicago, Harvard and Berkeley. He wrote widely, on legal philosophy, constitutional and international law, and political philosophy. Kelsen is best known for his *Pure Theory of Law* (*Reine Rechtslehre*) (1934). This is the basis of a theory which, with many changes, he espoused till he died.

ZENON BAŃKOWSKI

KEPLER, JOHANNES (1571–1630)

Kepler's mathematical analysis of Brahe's observations of the motions of Mars enabled him to formulate the descriptive 'laws' of planetary motion, thus giving heliocentric astronomy an empirical basis far more accurate than it had before. He insisted that astronomy had to discover the *causes* of the motions that the laws described, in this way becoming a 'physics of the sky'. In the pursuit of this goal, he formulated the notion of distance-dependent forces

between sun and planet, and guessed that gravity could be explained as an attraction between heavy bodies and their home planets, analogous to magnetic action, thus pointing the way for Newton's theory of gravity.

ERNAN MCMULLIN

KIERKEGAARD, SØREN AABYE (1813–55)

Introduction

Although Kierkegaard's name has come to be chiefly associated with writings on philosophical themes, his various publications covered a wide range that included contributions to literary criticism, discourses on specifically religious topics and forays into polemical journalism. Born in Copenhagen in 1813, he led an outwardly uneventful existence there until his death in 1855. None the less much that he wrote drew upon crises and turning points in his personal life; even his theoretical works often had an autobiographical flavour.

Kierkegaard held that the philosophy of his time, largely owing to the influence of Hegelian idealism, tended to misconstrue the relation of thought to reality, wrongly assimilating the second to the first; in doing so, moreover, it reflected an age in which habits of abstract reflection and passive response had blinded people to their true concerns as self-determining agents ultimately accountable for their own characters and destinies. He sought to counter such trends, exploring different approaches to life with a view to opening his reader's eyes both to where they themselves stood and to possibilities of opting for radical change. He implied that decisions on the latter score lay beyond the scope of general rules, each being essentially a problem for the individual alone; even so, his portrayal of the religious mode of existence presented it as transcending limitations experienced in alternative forms of life. Kierkegaard, himself an impassioned believer, was at the same time crucially concerned to articulate the Christian standpoint in a fashion that salvaged it from recurrent misconceptions. Rejecting all attempts to provide objective justifications or proofs of religious claims, he endorsed a conception of faith that eschewed rational considerations and consisted instead of subjective self-commitment maintained in the face of intellectual uncertainty or paradox. His account was set within a psychological perspective that laid stress upon freedom as an inescapable condition of action and experience. The complex implications he believed this to possess for the interpretation of pervasive human emotions and attitudes were discussed in works that later proved highly influential, particularly for the growth of twentieth-century existentialism. Here, as in other areas of his writing, Kierkegaard made a significant, though delayed, impact upon the course of subsequent thought.

1 Life

Kierkegaard was the youngest son of a prosperous and largely self-made Danish businessman. The father was a deeply religious but exacting and guilt-ridden individual who communicated his feelings of melancholy and anxiety to other members of his family; they certainly left a lasting impression on Kierkegaard's own character and development, causing him later to describe his upbringing as having been 'insane'. It was perhaps largely from a desire to please his father, towards whom he tended to exhibit an ambivalent mixture of love and fear, that at the age of seventeen he enrolled at the University of Copenhagen with the object of taking a degree in theology. Nevertheless, after passing his preliminary examinations he found himself increasingly attracted to other spheres of intellectual interest, particularly those involving developments in contemporary philosophy and literature; at the same time he cultivated a fashionably sophisticated lifestyle, following pursuits sharply at variance with the austere precepts that had been inculcated upon him at home. But in his journals, which he began during his protracted period as a student and continued to keep for the rest of his life, he is already to be found recording a growing dissatisfaction with the wayward mode of existence he had adopted, and the death of his father in 1838 appears finally to have prompted him to return to his academic studies with a view to settling down to a professional career. Thus by July 1840 he had been awarded his degree, and two months later he announced his engagement to marry Regine Olsen, the daughter of a highly placed civil servant. This, however, was not to be.

The story of Kierkegaard's abortive engagement is familiar from his journals, where he provided a detailed account of how he eventually broke off the relationship after an uneasy year during which he harboured regrets about his proposal. While his actual motives for making the final breach are left somewhat obscure, there can be no doubt as to its significance for his later thought and writings, allusions to it – often only lightly disguised – occurring in a variety of his works. In any case it certainly constituted a turning point. Henceforward he withdrew into a bachelor existence; moreover, although by now firmly committed to Christianity, he effectively abandoned any further thought of a clerical career and devoted himself instead to living as a writer on the very comfortable income he had inherited from his father's estate. The initial period of his authorship was in fact remarkably productive. He took less than a year over his master's dissertation *Om Begrebet Ironi* (*The Concept of Irony*), successfully submitting it to the university faculty in 1841, and he followed it with a series of books, all issued under pseudonyms, which were largely concerned with philosophical or psychological aspects of ethical and religious belief. The first, entitled *Enten-Eller* (*Either/Or*), came out in two substantial volumes in 1843 and was succeeded later in the same year by *Frygt og Baeven* (*Fear and Trembling*) and *Gjentagelsen* (*Repetition*); in 1844 *Philosophiske Smuler* (*Philosophical Fragments*) and *Begrebet Angest* (*The Concept of Anxiety*) appeared, and these in turn were followed by *Stadier paa Livets Vej* (*Stages on Life's Way*) in 1845 and by *Afsluttende uvidenskabelig Efterskrift* (*Concluding Unscientific Postscript*) in 1846. Two further pseudonymous works on connected themes, *Sygdommen til Døden* (*The Sickness unto Death*) and *Indøvelse i Christendom* (*Training in Christianity*), were published in 1849 and 1850 respectively.

Although it is the writings listed above that have chiefly attracted the attention of subsequent philosophers and commentators, they by no means exhaust the total of Kierkegaard's literary output during the 1840s. Apart from some critical pieces, he also produced – this time under his own name – a number of directly religious discourses in which he aimed to present the essentials of Christian teaching; thus such works as his *Opbyggelige Taler i forskjellig Aand* (Edifying Discourses in Various Spirits) of 1847 were expressly designed to communicate and illustrate the true nature of the Christian message and the demands it imposed upon the individual. In their uncompromising emphasis on the severity of these requirements, and in their manner of stigmatizing the complacency and 'double-mindedness' imputable to contemporary representatives of the faith they professed to serve, the latter books can be said to foreshadow the standpoint from which, in the culminating phase of his career, he launched a violent assault upon the established Church of Denmark. The occasion for this was the death of the Danish primate, Bishop Mynster, in 1854. Kierkegaard had increasingly come to regard Mynster as exemplifying in his own person many of the shortcomings of the Church as a whole, and he was therefore incensed by hearing the dead prelate pronounced instead to have been a 'witness to the truth'. As a result he set out in the following months to denounce the covert worldliness and hypocrisy that permeated the clerical establishment, first through articles in the public press and subsequently in a broadsheet printed at his own expense. The ferocity of his attacks, appearing after a spell when he had published relatively little, caused surprise and some consternation. The controversy they stirred up was, however, abruptly interrupted by Kierkegaard's sudden collapse in October 1855 and his death a few weeks later.

2 The limits of objectivity

In an early entry in his journals, written when he was still a student, Kierkegaard gave vent to the dissatisfaction he felt at the prospect of a life purely devoted to the dispassionate pursuit of knowledge and understanding. 'What good would it do me', he then asked himself, 'if truth stood before me, cold and naked, not caring whether I recognized her or not?' Implicit in this question was an outlook which was to receive mature articulation in much of his subsequent work, being particularly prominent in his criticisms of detached speculation of the kind attributable to those he called 'systematists and objective philosophers'. To be sure, and notwithstanding what has sometimes been supposed, he had no wish to be understood as casting aspersions on the role played by impersonal or disinterested thinking in studies comprising scholarly research or the scientific investigation of nature: such an approach was quite in order when adopted within the limits set by determinate fields of enquiry. But matters were different when philosophical attempts were made to extend it in a manner that purported to transcend all particular viewpoints and interests, this conception of the philosopher's task leading to the construction of metaphysical theories which sought to comprehend every aspect of human thought and experience within the disengaged perspective of objective contemplation. Kierkegaard considered Hegel to be the foremost contemporary representative of the latter ambition, the famous system to which it had given rise being in his opinion fundamentally misconceived.

Kierkegaard's general reaction to what he found unacceptable in the Hegelian theory is in fact crucial to an understanding of his own philosophical position. On his interpretation Hegel's philosophy ultimately rested upon a central error, one that involved the illicit identification of essence and existence, thought and reality. The German writer had endeavoured to exhibit the world, and the place of humanity within the world, in terms of an evolving sequence of logical categories that rendered its overall structure fully intelligible from the impersonal standpoint of pure reason (see HEGEL, G.W.F. §§4–8). Kierkegaard disclaimed any desire to dispute the considerable ingenuity of the Hegelian metaphysic when this was regarded simply as an 'experiment in thought'. He insisted, however, that thought was not the same as reality, nor could anything real be validly deduced from it; in particular, it was altogether mistaken to suggest that changes and developments in the sphere of actual existence were assimilable to dialectical transitions between timeless concepts – it was one thing to construct a self-contained logical or formal system, quite another to entertain the project of producing an existential one. In raising such objections, moreover, he was especially concerned to stress their relevance to Hegel's treatment of specifically human existence. The Hegelian world-picture presupposed the possibility of adopting an absolute, God-like point of view from which everything was seen as contributing to an interlocking and rationally determined totality; as a result, human nature tended to be reduced to a philosophical abstraction, the individual to a representative of the species, and the significance of a particular person's life and actions to their role in forwarding an all-encompassing historical process that overshadowed and transcended them. At the same time, Kierkegaard suggested that the notion of an impersonal 'knowing subject' of the type postulated by thinkers of the Hegelian school was symptomatic of a corresponding inclination to forget that the speculative philosopher was himself an 'existing human being' whose status and situation imposed necessary limits upon his outlook and cognitive credentials. Far from his viewpoint on the world being from nowhere within it, such a philosopher inescapably belongs to it in his capacity as a finite empirical individual who 'sleeps, eats, blows his nose' and who has 'to face the future'.

Although Kierkegaard's attitude to Hegel is most extensively displayed in the polemical references that enliven the pages of his *Concluding Unscientific Postscript*, scattered allusions to the faults and weaknesses of 'the System' also appear in many of his other writings. The number and variety of the contexts in which they occur indicate that he regarded the current vogue of Hegelianism as having more than a purely academic significance, the popularity it enjoyed at once reflecting and helping to promote a contemporary ethos in which what he termed the 'illusions of objectivity' exercised a pervasive and corrupting influence. Thus he conceived the age to be one wherein people had lost a clear sense of their identity as individuals ultimately responsible for their own characters, outlooks and modes of living. Instead it was customary for them to take refuge in the anonymity provided by membership of collective movements or trends and to envisage themselves as being inevitably circumscribed by the social roles they occupied in a manner that absolved them from personal accountability for their pronouncements or actions. In Kierkegaard's view, they had largely forgotten what 'it means for you and me and him, each for himself, to be human beings', succumbing to a 'quantitative dialectic' in which a bemused preoccupation with large-scale historical events and a passive submission to the levelling influence of 'the crowd' took precedence over the vital constituents of human life and experience – 'the inner spirit, the ethical, freedom'.

Confronted by such tendencies, Kierkegaard considered it to be a primary part of his task as a writer to challenge habits of thought that smothered spontaneous feeling and obstructed active commitment. He held that these had had a particularly deleterious effect in the religious sphere; the widespread belief that the fundamental tenets of Christianity could be rationally interpreted and objectively justified within the framework of the Hegelian system was symptomatic of a more general disposition to treat both religion and morality alike in a blandly contemplative spirit that detached them from the contexts of inward conviction and practical engagement to which they essentially belonged. With this in mind it was necessary in the first instance to 'make people aware', bringing home to them the limitations of their present condition and awakening them to the possibility of subjective self-determination and change.

3 Aestheticism and the ethical

Kierkegaard maintained that in his early writings he had aimed to arouse and enlarge the self-understanding of his readers by eschewing abstract instruction and by employing in its place an avowedly therapeutic method he referred to as 'indirect communication'. This meant delineating particular ways of life in a fashion that enabled people to grasp concretely and from within the distinct types of outlook and motivation involved, such a procedure being a characteristically literary

or 'poetic' one. Not only were alternative positions imaginatively presented as if in a novel or play; the books in which this was done were attributed to different personages in the shape of pseudonymous authors or editors. He intended thereby to avoid the kind of *ex cathedra* didacticism he associated with standard philosophical texts of his time. Instead he favoured an undogmatic approach in which competing views and attitudes were 'allowed to speak for themselves', it being left to his readers to decide where they stood in relation to these and to make up their own minds about the practical conclusions to be drawn.

Either/Or was the first of Kierkegaard's works to be published under a pseudonym and was a book he later alluded to as clearly exemplifying his use of the above method. It purports to portray two radically dissimilar modes of existence, one characterized as 'aesthetic' and the other as 'ethical'. Both are presented through the medium of allegedly edited papers or letters, the first set being ascribed to an individual referred to as 'A' and the second to an older man who is said to be by profession a judge. Aestheticism as exhibited in A's loosely related assortment of papers is seen to take on a lively variety of forms and guises; among other things, it is held to find expression in the characters of legendary figures like Don Juan and Faust, and it is also illustrated by an account in diary form of a step-by-step seduction. By contrast, the position of the ethicist is set out in two somewhat prosaic letters which are addressed by the Judge to A and which include detailed critical analyses of the younger man's motives and psychological prospects.

What did Kierkegaard understand by the categories he distinguished? From the text the aesthetic life emerges as one in which the individual is essentially concerned with exploring means to his own satisfaction and where there is a consequent absence of overall continuity in the course he follows. As has been indicated, however, the picture drawn is complex and multi-faceted. While in general outline it is suggestive of a person in pursuit of transient pleasures rather than following any long-term aim, there are passages where attention is chiefly focused on the aesthetic individual's dependence upon unpredictable vicissitudes of mood or circumstance, and others again where emphasis is laid on his need to guard against the threats posed by ennui or melancholy. Not unexpectedly, it is the problematic possibilities inherent in A's lifestyle that the Judge singles out for criticism in his comprehensive survey of the aesthetic position. Whereas the aestheticist typically allows himself to be swayed by what he conceives to be the unalterable constituents of his natural disposition, the ethically orientated individual is prone to look at himself in an altogether different light. Both his motivation and behaviour are responsive to a self-image 'in likeness to which he has to form himself', his particular aptitudes and propensities being seen as subject to the control of his will and as capable of being directed to the realization of demanding projects that reflect what he truly aspires to become. It is commitment to such projects which endows the ethical life with a coherence and self-sufficiency that its aesthetic counterpart conspicuously lacks.

Kierkegaard's treatment in *Either/Or* of the aesthetic/ethical contrast is frequently thought to echo the Kantian distinction between inclination and duty (see Kantian ethics). But although there may be discernible affinities, there are also significant differences. Thus Kant's predominantly schematic accounts of sensuous motivation are devoid of both the psychological penetration and the literary sophistication that characterize Kierkegaard's wide-ranging portrayals of the aesthetic stance. And comparable divergences are apparent in the case of the ethical. Kierkegaard's judge may be said to follow the German philosopher in highlighting the role of the will, underlining its independence of contingent circumstances and stressing its capacity to manage the sphere of natural inclination in a way that is conformable to the ethical individual's paramount concerns. Yet while he shares Kant's belief in and respect for the latter's autonomy, he differs in not presenting moral requirements in terms of the purely formal prescriptions of practical reason. The self which it is the task of each individual to choose and develop is not an 'abstract' but a 'concrete' self; it stands in 'reciprocal relations' with its actual social and cultural surroundings, things like marriage, having a job and undertaking civic and institutional responsibilities being intrinsic to personal fulfilment in the requisite sense. It is implied, moreover, that such active participation in communal affairs, involving an unconstrained and inward adherence to standards presupposed by a shared form of life, reinforces the contrast already drawn with the unreflective or wayward 'experimentalism' typified by certain manifestations of the aesthetic outlook. Thus the Judge insists upon the conceptual exclusion from the ethical of whatever savours of the arbitrary or the merely capricious. At the same time, however, he indicates that this should not be thought of as circumscribing in any fundamental fashion the subjective freedom and independence of the individual. For although moral requirements must of necessity be treated as authoritative, they are not apprehended as deriving from a source 'foreign to the personality' but are instead experienced as springing or 'breaking forth' from the latter's essential nature.

Even so, it is arguable that the internal tensions between individualistic and socially conformist strains discernible in the Judge's representation of the ethical sphere cannot always be easily or satisfactorily resolved. Kierkegaard discussed one context in which they might be said to arise in a critical form when he went on to consider a way of life that constituted an alternative to the possibilities so far portrayed. This stage of existence, transcending the other two, was the religious.

4 The religious consciousness

Central to Kierkegaard's account of religion is his treatment of the concept of faith, a treatment that throws into relief the most distinctive features of his philosophical standpoint. There are two main areas in which these manifest themselves and in which it is the crucial inadequacies of human reason, practical as well as theoretical, that are emphasized.

The first concerns limitations in the outlook of accepted morality that make themselves felt at certain levels or junctures of experience and are held to call for what is termed a 'teleological suspension of the ethical'. The implications of this *prima facie* puzzling notion are explored in *Fear and Trembling*, an intricately wrought study in which Kierkegaard's pseudonymous author – Johannes *de silentio* – treats as his central theme the biblical story of Abraham and Isaac. Johannes portrays Abraham as being ostensibly called upon to set aside ethical concerns in deference to a higher *telos* or end that altogether transcends them. Such a situation is contrasted with the predicament of what he terms the 'tragic hero', the latter being someone who is forced to make a choice between conflicting moral requirements but who in doing so still remains within the bounds of the ethical domain. Thus although the decisions taken there may be at an agonizing cost, the fact that they can none the less be seen to conform to universally recognized norms renders them rationally acceptable to others and capable of gaining their respect. This, however, is not so in the case of Abraham, who, as a solitary 'knight of faith', responds to a divine command supposedly addressed to himself alone and having a content – the killing of his own son – that must inevitably strike ordinary thought as being both outrageous and incomprehensible. No attempt is made to soften the paradoxical character of such points. On the contrary, Kierkegaard's pseudonym sets out to underline, indeed to dramatize, the disturbing nature of the demands which religious faith can impose on the life and conduct of an individual. At the same time, he takes practising churchmen severely to task for paying lip service to a phenomenon whose awesome significance they fail to appreciate, and he also criticizes contemporary theorists of religion for construing an intrinsically transcendent category in terms drawn from social and essentially secular conceptions of ethics. This was not to suggest that from a religious point of view moral standards and principles could in general be abrogated or overruled. It did mean, on the other hand, that within that perspective they took on a radically different aspect, one where they possessed a relative rather than an absolute status and where it was the individual's own relation to God that was paramount, assuming precedence over all other considerations.

The claim that faith in the religious sense pertains to what exceeds the limits of human rationality and understanding recurs in the two subsequent writings that Kierkegaard referred to as his 'philosophical works' – *Philosophical Fragments* and *Concluding Unscientific Postscript*. Here, however, it is discussed within a wider setting and in connection with theoretical questions concerning the proper interpretation of religious assertions. Although once again ascribed to a pseudonym, albeit a different one, both books appeared under Kierkegaard's imprint as their 'editor' and in any case may be taken to have expressed views that were basically his own. Thus in each of them it is made apparent that the author totally rejects the feasibility of trying to provide religious tenets with an objective foundation. The belief that the existence and nature of God could be conclusively established from resources supplied by pure reason might have enjoyed a long philosophical career; none the less it was demonstrably unacceptable, Kierkegaard largely echoing – though in a summary form and without attribution – some of the objections that Kant had levelled against arguments traditionally advanced by theologians and metaphysicians. Nor was he any more receptive to the suggestion that religious claims of a specifically historical character, such as those relating to the doctrines of Christianity, were susceptible to justification on straightforwardly empirical grounds; it was impossible to regard them as representing ordinary historical facts of the sort to which standard appeals to inductive inference and evidence would normally be considered appropriate. As he acknowledged, Lessing and Hamann were thinkers who in different ways had already underlined the problematic issues raised by the latter. But it was perhaps Hume's contention in his first *Enquiry* that only a 'miracle in his own person', subverting all the principles of his understanding, could bring a reasonable individual to embrace the Christian religion which most strikingly foreshadowed Kierkegaard's approach to the subject. No doubt Hume himself had intended his words to be taken in a strictly ironical sense. Even

so, Kierkegaard implied that it was open to believers to look at sceptical asides of the type cited in a different light. For by exposing the vanity of attempts to encompass within its grasp matters that lay beyond the scope of reason, such remarks could be said to provide salutary reminders of what was really at stake. It was not to the spheres of impersonal judgment and dispassionate assent that the religious consciousness rightfully belonged, but on the contrary to those of individual choice and inner commitment.

5 Faith and subjectivity

Kierkegaard was certainly not alone in suggesting that writers who tried to justify religious belief on cognitive grounds were more confused about its true nature than some of their sceptically minded critics and to that extent posed a greater threat to it; indeed, Kant himself had virtually implied as much when he spoke of denying knowledge to make room for faith, as opposed to seeking to give religious convictions a theoretical foundation that could only prove illusory (see KANT, I. §4). The question arose, however, of what positive account should be given of such faith, and here Kierkegaard's position set him apart from many thinkers who shared his negative attitude towards the feasibility of providing objective demonstrations. As he made amply clear, the religion that crucially concerned him was Christianity, and far from playing down the intellectual obstacles this ostensibly presented he went out of his way to stress the particular problems it raised. Both its official representatives and its academic apologists might have entertained the hope of making it rationally acceptable to a believer, but in doing so they showed themselves to be the victims of a fundamental misapprehension. From an objective point of view, neither knowledge nor even understanding was possible here, the proper path of the Christian follower lying in the direction, not of objectivity, but of its opposite. It was only by 'becoming subjective' that the import of Christianity could be grasped and meaningfully appropriated by the individual. Faith, Kierkegaard insisted, 'inheres in subjectivity'; as such it was in essence a matter of single-minded resolve and inward dedication rather than of spectatorial or contemplative detachment, of passion rather than of reflection. That was not to say, though, that it amounted to a primitive or easy option. On the contrary, faith in the sense in question could only be achieved or realized in the course of a person's life at great cost and with the utmost difficulty (see FAITH).

To understand what lay behind this claim it is important to recognize that Kierkegaard broadly distinguished between two levels or stages of development at which religious belief manifested itself. In his account of the first of these, in which he specified the criteria that any standpoint must conform to if it was to count as a religious one, he was at pains to emphasize the element of 'objective uncertainty' surrounding assertions about the transcendent, such uncertainty deriving from the absence of rational support previously alluded to. So construed, faith essentially involved personal venture or risk, preserving it being figuratively compared to 'remaining out upon the deep, over seventy thousand fathoms of water'. But to hold fast to a conviction in the face of a lack of objective justification or grounds was not the same as giving assent to something that appeared to be intrinsically contrary to reason, an 'offence' to the understanding itself. And it was in the latter terms that Kierkegaard referred to the Christian conception of the incarnation, this being an 'absolute paradox' that required the believer to 'risk his thought' in embracing its reality. Moreover, it was in the light of such a requirement that the level of faith aspired to in Christianity could be said to constitute 'the highest passion in the sphere of human subjectivity', exceeding other forms of religious belief in virtue of the unique nature of the demands it made upon an individual's mind and outlook.

According to Kierkegaard, the paradox of the incarnation lay in the notion that the eternal or timeless had entered the sphere of finite and temporal existence: this amounted to uniting contradictories in a fashion that meant a 'breach with all thinking'. Such a feature precluded treating it as if it could be vouchsafed by ordinary historical enquiry, and he set aside the scholarly pursuit of biblical research and criticism as altogether irrelevant to what was here at issue; quite apart from the specifically 'approximative' status he assigned to history as a branch of knowledge, the content of the particular 'hypothesis' under consideration defied logic in a way that contravened the principles governing any kind of accredited cognitive discipline. Furthermore, he regarded its paradoxical character as having another crucial consequence, namely, that there was no basis for the common assumption that the contemporary witnesses of what was recorded in the Gospels were in a better position to authenticate the reality of the incarnation than subsequent generations who had only the testimony of others to rely on. To suppose that in the present case the evidence of direct observation was superior to testimony was to fail to see that neither could ever function as more than an 'occasion' for belief of the sort of question. With both, a volitional leap of faith was necessary, one that involved a 'qualitative transition' from the

realm of rational thought into that of the intellectually inaccessible or 'absurd'.

Kierkegaard's stress on the gap separating faith from reason, which it could need divine assistance to surmount, was reflected in the controversial account he offered of religious truth; this likewise received a subjective interpretation. Thus in a well-known passage in the *Postscript* he contrasted two distinct ways of conceiving of truth, one treating it as a matter of a belief's corresponding to what it purported to be about and the other as essentially pertaining to the particular manner or spirit in which a belief was held. And it was to the second of these conceptions that he ostensibly referred when he declared that 'subjectivity is the truth', genuineness of feeling and depth of inner conviction being the decisive criterion from a religious point of view. Admittedly he has sometimes been criticized here for a tendency to shift from construing religious truth along the above lines to doing so in terms of the objective alternative, with the questionable implication that sheer intensity of subjective acceptance was sufficient to authenticate the independent reality of what was believed. But however that may be, it is arguable that in this context – as is often the case elsewhere – his prime concerns were conceptual and phenomenological in character, rather than epistemic or justificatory. Kierkegaard's central aim was to assign Christianity to its proper sphere, freeing it from what he considered to be traditional misconceptions as well as from the falsifying metaphysical theories to which there had more recently been attempts to assimilate it. If that meant confronting what he himself called 'a crucifixion of the understanding', the only appropriate response from the standpoint in question lay in a passionate commitment to the necessarily paradoxical and mysterious content of the Christian religion, together with a complementary resolve to emulate in practice the paradigmatic life of its founder.

6 Psychological themes and influence

Kierkegaard's preoccupation with the category of subjectivity that ran like a continuous thread through his theoretical writings was integrally linked to his conception of human beings as individual and self-determining participants in the 'existential process'. The view that freedom and the possibility of change constituted fundamental conditions of human life and fulfilment was delineated in his so-called 'psychological works', *The Concept of Anxiety* and *The Sickness Unto Death*. In both books the structure of human personality is portrayed in developmental and volitional terms; individuals exist in the mode, not of being, but of becoming, and what they become is something for which they themselves are ultimately responsible. In this connection certain pervasive attitudes and emotions can be seen to possess a special significance, Kierkegaard giving priority of place to a form of anxiety or dread (*Angst*) which differed from sentiments like fear in lacking any determinate object and in being directed instead to 'something that is nothing'. Such a state of mind might manifest itself in a variety of ways, but he made it clear that his fundamental concern was with its relation to the consciousness of freedom. Thus he referred to the particular kind of dizziness, or vertiginous ambivalence between attraction and repulsion, that was liable to afflict us when, in certain circumstances, the realization dawned that there was nothing objective that compelled us to opt for one course of action rather than another; in the last analysis what we did was up to ourselves alone, freedom being said to 'look down into its own possibility' as though into a yawning abyss or void. Kierkegaard believed that the psychological phenomenon so identified had momentous consequences, not least for its bearing on the religious alternatives of sin and salvation. On the one hand, the story of Adam represented a mythical illustration of how the awakened consciousness of freedom could arouse an anxiety whose occurrence in this case was the precursor of sin. On the other hand, however, such an emotion might also arise when there was a possibility of making a qualitative leap, not into sin and alienation from God, but towards the opposite of this, namely, faith and the promise offered by Christianity. But here Kierkegaard reiterates the point that a presentiment of the difficulties and sacrifices entailed made the latter a course which there were strong temptations to resist; it followed that people were only too prone to conceal from themselves their potentialities as free beings, such self-induced obscurity serving as a convenient screen for inaction and a failure to change. Self-deception of this sort in fact formed a component of many of the varieties of spiritual despair which Kierkegaard picked out for analysis, as well as underpinning his diagnosis of some of the broader types of malaise he detected in the social and cultural climate of his time.

In his insistence upon the ultimacy of human freedom and his correlative attention to the devices and strategies whereby people may seek to protect themselves from a recognition of some of its disturbing implications, Kierkegaard anticipated themes that were taken up, albeit much later and often in an explicitly secular setting, by a number of leading twentieth-century writers (see Existentialism). Subjectivity and the primacy of the individual, the 'burden' of freedom, the contrast between authentic

and inauthentic modes of existence – these and associated topics became familiar through the works of existentialist philosophers such as Jean-Paul Sartre and Martin Heidegger as well as figuring in the wider field of imaginative literature. Nor were those the only areas in which his ideas eventually made an impact. In the sphere of ethics his emphasis on radical choice indirectly contributed to the growth of non-cognitivist theories of value, while in religion his conception of faith had a profound influence on the development of modern Protestant theology, notwithstanding understandable reservations about some of his more extreme claims regarding its paradoxical character.

KNOWLEDGE AND JUSTIFICATION, COHERENCE THEORY OF

Introduction

Coherence theories of justification represent one main alternative to *foundationalist* theories of justification. If, as has usually been thought, possessing epistemic justification is one necessary condition (along with truth and perhaps others) for a belief to constitute knowledge, then a coherence theory of justification would also provide the basis for a coherence theory of knowledge. While some proponents of coherence theories have restricted the scope of the theory to empirical justification, others have applied it to all varieties of epistemic justification. (There are also coherence theories of meaning and of truth, as well as coherence theories of ethical or moral justification.)

The initial contrast between coherence theories and foundationalist theories arises in the context of the *epistemic regress problem*. It is obvious that the justification of some beliefs derives from their inferential relations to other, putatively justified beliefs, and that the justification of these other beliefs may depend on inferential relations to still further beliefs, and so on, so that a potential regress of epistemic justification looms, with scepticism as the threatened outcome. The foundationalist solution to this problem is that one arrives sooner or later at basic or foundational beliefs: beliefs that are epistemically justified, but whose justification does not derive from inferential relations to any further beliefs and so brings the regress to an end. The defining tenet of a coherence theory of justification is the rejection of this foundationalist solution, the coherentist insisting that any belief (of the kinds to which the theory is applied) depends for its justification on inferential relations to other beliefs and eventually to the overall system of beliefs held by the believer in question. According to the coherentist, the justification of this system of beliefs is logically prior to that of its component beliefs and derives ultimately from the *coherence* of the system, where coherence is a matter of how tightly unified or interconnected the system is by virtue of inferential connections (including explanatory connections) between its members.

Contrary to what this might seem to suggest, coherence theories do not deny that sensory observation or perception plays an important role in justification. What they do deny is that this role should be construed in a foundationalist way, insisting instead that the justification of observational beliefs ultimately derives also from considerations of coherence. Specific coherence theories may also add other requirements for justification, thereby departing from a pure coherentism, while still avoiding foundationalism.

While the idea of a coherence theory has often played the role of a dialectical foil, developed theories of this kind are relatively rare and are often in serious disagreement among themselves. In this way, coherentism is much less a unified view with standard, generally accepted features, than is foundationalism.

1 History

In contrast to foundationalism, the coherence theory of justification is a relatively recent innovation in the

history of philosophy. Although it is possible, albeit with some strain, to construe Spinoza and Kant as advocating versions of coherentism, the first relatively clear-cut coherentist positions are those of the late nineteenth- and early twentieth-century absolute idealists, especially F.H. Bradley and Bernard Bosanquet. Unfortunately, however, the views of these philosophers are marked by a pervasive failure to distinguish epistemological and metaphysical issues, making it hard to separate their coherence theories of justification from their distinct, though related, advocacy of coherence theories of the nature of truth. (A more recent version of essentially the same position, in which this distinction is clearly drawn, is found in the work of Brand Blanshard.)

Coherentism was also advocated in the 1930s by some of the logical positivists, mainly Otto Neurath and Carl Hempel, in response to the foundationalist views of Moritz Schlick. Neurath identifies coherence with mere logical consistency; he also, while retaining something like a justificatory appeal to observation, in effect identifies observational beliefs solely by reference to their content. He thus has no apparent response to what is perhaps the most central and obvious objection to coherence theories: that there will always be indefinitely many different coherent systems between which a coherence theory will provide no basis for a reasoned choice (see below). Hempel avoids this problem to some extent by simply identifying observational beliefs as those beliefs with the right sort of content that are accepted by 'the scientists of our culture circle', but is able to offer no real rationale for such an identification. He also, like the idealists, fails to distinguish in any clear way between a coherence theory of justification and a coherentist account of the nature of truth.

More recent coherentist positions, in contrast, generally repudiate the coherence theory of truth entirely and are more explicitly and narrowly epistemological in their character and motivation. The main arguments offered in their favour almost always derive from perceived objections to foundationalism, perhaps the central one being the charge that the foundationalist can account for the status of the allegedly basic or foundational beliefs as genuinely justified (in the sense of there being some reason or basis for thinking them to be true) only by appealing to justificatory premises of some sort and so destroying the status of such beliefs as foundational (see Foundationalism). Thus coherentists insist that there is no way to appeal for justification to anything outside of one's system of beliefs because any such supposed source of justification would have to be apprehended by the person in question in a belief or belief-like state before it could play any justificatory role, and then it would be the belief rather than the external item that was the immediate source of justification.

As this suggests, coherentist positions are virtually always internalist rather than externalist in character, in that they insist that the basis for epistemic justification must be cognitively accessible to the believer in question; while an externalist version of coherentism is theoretically possible, it would have little philosophical point, since a foundationalist view would be vastly more straightforward if externalism were otherwise acceptable (see Internalism and externalism in epistemology).

These recent coherentist views differ from each other in a wide variety of ways, and often seem to have little in common beyond their rejection of foundationalism and their invocation in some fashion of the idea of coherence (and indeed there is often room for doubt in a particular case about how thoroughgoing the former of these two aspects really is). Coherentism is one ingredient, though never developed in a fully systematic way, in the comprehensive and difficult philosophical system of Wilfrid Sellars. The epistemological position of W.V. Quine is also frequently described as coherentist in character, though other features of Quine's position, especially his claim that epistemology should be naturalized (reduced to psychology), make it difficult to decide whether his view is genuinely a version of coherentism, as opposed to a qualified version of foundationalism (see Naturalized epistemology). More overtly coherentist positions have been advocated by Gilbert Harman (influenced especially by Quine), Nicholas Rescher, Keith Lehrer, and Laurence BonJour (influenced especially by Sellars).

As the foregoing suggests, coherence theories first arise as dialectical alternatives to foundationalism, rather than as views that are claimed to be initially plausible on their own. Their defence and elaboration must confront a number of standard problems and objections, with which any such view must seemingly deal in some fashion, and it is around these that the present entry is organized.

2 The regress problem and non-linear justification

The first standard problem arises from the epistemic regress problem itself. If foundationalism is repudiated (and if a genuinely infinite regress of justification is also rejected as psychologically impossible and in any case tantamount to scepticism), then the only remaining possibility for the outcome of the initial regress of epistemic justification seems to be a circle in which the chains of justification eventually loop back upon themselves. Incautious advocates of coherentism have sometimes seemed to

endorse the idea that such a result is acceptable if only the circles are 'large enough'. But the obvious objection to circular chains of justification, to which the size of the circle seems irrelevant, is that they involve circular reasoning and hence have no genuine justificatory force. This is essentially the reason that foundationalists give for rejecting the coherentist alternative and taking the regress problem to constitute a decisive argument for foundationalism.

Perhaps the most standard coherentist response to this issue, stemming originally from Bosanquet, is to reject the idea, implicit in most presentations of the regress problem, that relations of justification must involve a linear, asymmetrical order of dependence among the beliefs in question. They insist instead that justification, when properly understood, is ultimately holistic and non-linear in character, with all of the beliefs in the system standing in relations of mutual support, but none being epistemically prior to the others. In this way, it is alleged, any true circularity is avoided. Such a view amounts to making the system itself the primary unit of justification, with its component beliefs being justified only derivatively, by virtue of their membership in an appropriate sort of system. And the property of the system, in virtue of which it is justified, is of course specified as coherence.

3 The concept of coherence

But what exactly is coherence? A second obvious problem for a coherence theory is to explicate and clarify this central concept. Intuitively, coherence is a matter of how the beliefs in a system of beliefs fit together or dovetail with each other, so as to constitute one unified, organized, and tightly structured whole. And it is clear that this fitting together depends on a wide variety of logical, inferential and explanatory relations among the components of the system. But spelling out the details of this idea, particularly in a way that would allow unproblematic assessments of comparative coherence, turns out to be extremely difficult, in part at least because of its obvious dependence on more specific and still unsettled topics, such as induction, confirmation, probability and explanation.

The strongest and most demanding conception of coherence, advocated by the idealists, specifies a coherent system of beliefs as one in which each member entails and is entailed by all of the others. It seems clear, however, that this strong conception is both unrealizable by any actual system of beliefs imaginable and also of dubious cognitive value, since it would seem to make all of the beliefs but one redundant and dispensable. (These problems may be mitigated somewhat, though certainly not eliminated, by remembering that the idealists have a quite broad conception of entailment, one in which, for example, relations of nomological necessity are regarded as a kind of entailment.)

At the opposite extreme, it seems equally mistaken to follow Schlick and some others in identifying coherence with mere logical consistency, since the beliefs of a logically consistent system might be entirely unrelated to each other, thus yielding no real degree of mutual support and no apparent reason for thinking that any of them are true. Somewhat more surprisingly, it also seems to be a mistake to make complete logical consistency even an absolutely *necessary* condition for any degree of coherence, as many coherentists have done. In light of such things as the preface paradox and general human fallibility, this would probably mean that few if any actual systems of belief are coherent to any degree at all, a result that seems unacceptably paradoxical (see Paradoxes, epistemic).

If there is a tenable conception of coherence along these general lines, it must seemingly fall somewhere between the two extremes just discussed. Coherence will be a matter of degree, with logical consistency being a highly relevant but not absolute criterion. Coherence will also require a high degree of inferential interconnectedness in the system, involving relations of necessitation, both strictly logical and otherwise, together with probabilistic connections of various kinds. An important aspect of this is what might be called probabilistic consistency, that is, the absence of relations between beliefs in the system in virtue of which some are highly unlikely to be true in relation to others. A further important ingredient of coherence that is much emphasized in recent discussions is the presence of explanatory relations among the components of the system, thus reducing the degree to which the beliefs of the system portray unexplained anomalies. (If 'inference to the best explanation' is accepted as one species of inference, then such explanatory relations can be viewed as a kind of inferential relation – see Inference to the best explanation.) Indeed, some positions such as that of Harman, and perhaps also Sellars, go so far as to virtually identify coherence with the presence of such explanatory relations.

The foregoing is an approximate account of the historically standard conception of coherence. While some proponents of coherentism have employed essentially this conception, others have in effect devised more idiosyncratic conceptions of coherence, conceptions whose connection to the historical concept is often quite tenuous. In particular, Rescher in fact employs both the standard conception of coherence, for certain purposes, and also a quite different concept that involves forming

maximally consistent subsets of initially conflicting 'data' or 'truth-candidates', and then choosing among these subsets in a variety of ways that involve no appeal to standard coherence. And Lehrer (1974, 1990) has offered two subtly different versions of a general view that defines coherence in relation to the believer's own subjective conception of probability or relative likelihood of truth; for a belief to cohere with the person's system of beliefs is roughly for it to be judged to be more probable or more reasonable than any relevant competitor.

The precise nature of coherence remains a largely unsolved problem. It is important to see, however, that difficulties in this area cannot yield anything like a decisive argument against coherence theories and in favour of their foundationalist rivals. This is so because the concept of coherence, or something so similar to it as to be capable of playing essentially the same role, is also an indispensable ingredient in virtually all foundationalist theories: coherence must seemingly be invoked to account for the relation between the basic or foundational beliefs and other non-foundational or 'superstructure' beliefs, in virtue of which the latter are justified in relation to the former. For this reason, giving an adequate account of coherence should not be regarded as exclusively or even primarily the responsibility of coherentists, despite the central role that the concept plays in their position.

4 Coherence and observation

As mentioned above, few if any coherentists have wished to deny the seemingly obvious fact that sensory observation or perception plays a crucial role in justification (although they have not always been fully explicit on this point). It is thus incumbent on a coherence theory to explain how such observation can be construed in a non-foundationalist way. The central idea is that a belief that is produced by the senses, rather than being arrived at inferentially, might still depend for its justification on coherence with the background system of beliefs. But it is crucial here that the justification in question should still depend also in some way on the fact that the belief was a result of perception, since justification that depended only on the coherence of the belief's propositional content with the rest of the cognitive system would make the observational status of the belief irrelevant.

One way to develop this idea is to focus on the fact that observational or perceptual beliefs are *cognitively spontaneous*; they simply strike the observer in an involuntary, coercive, non-inferential way, rather than as a product of any sort of inference or other discursive process, whether explicit or implicit. That a belief has this status, however, says nothing so far, according to the coherentist, about whether or how it is justified. Indeed, there is no reason to think that all cognitively spontaneous beliefs *are* justified, or even necessarily that most of them are, since the category would include hunches and irrational spontaneous convictions, as well as beliefs resulting from perception. But suppose that, as seems to be the case with most ordinary systems of belief, the system includes a belief to the effect that specific kinds of cognitively spontaneous beliefs (identified by their general subject matter, by their apparent mode of sensory production as reflected in the content of the belief, and by concomitant factors of various kinds) are, under specified (or perhaps 'normal') conditions, highly likely to be true. It then becomes possible to give a justifying reason for such a belief that appeals to its status as cognitively spontaneous and putatively observational, but still does so in a way that depends on the coherence with the background system of beliefs of the claim that a belief of this kind and produced in this way is true. Such a belief would be arrived at non-inferentially, but still justified by appeal to inference relations and coherence. (This view of observation is most explicit in BonJour (1985), but something like it seems implicit in Blanshard's talk of 'beliefs about the technique of acquiring beliefs', in Sellars's talk of 'language-entry transitions', in Quine's talk of the 'observational periphery' of the 'web of belief', in Rescher's idea of 'data', and in Lehrer's (1974, 1990) discussion of a person's trustworthiness in acquiring certain kinds of information).

The foregoing provides at best only the beginning of a coherentist account of observation, leaving various problems to be solved that can only be touched on here. First, the other beliefs needed to give a justifying reason for a particular observational belief must themselves be justified in some fashion, without relapsing at this point into foundationalism. These beliefs will include at least: (1) beliefs about the conditions; (2) the general belief about the reliability of the kind of cognitively spontaneous belief in question; and (3) beliefs about the occurrence of that particular belief, including the belief that it was indeed cognitively spontaneous. The justification for (1) will presumably have to include other observational beliefs, themselves justified in the same general fashion, so that any case of justified observation will normally or perhaps always involve a set of mutually supporting observations. The justification for (2) will appeal inductively to other cases of correct observation, as judged from within the system, as well as to more theoretical reasons for thinking that beliefs of the kind in question are generally produced in a reliable

way. The justification for (3) will appeal to introspective beliefs, themselves constituting a species of observation, and ultimately to the believer's comprehensive grasp of their overall system of beliefs – a grasp whose status poses one of the main problems to be considered below.

Second, it is not enough for the justification of an observational belief that a reason of the foregoing sort should merely be present in a person's system of beliefs, since such an individual might completely fail to notice that this was so, and might hold the belief on some other basis or for no reason at all. Thus even though the observational belief is not arrived at by inference, the availability of the inferential justification in question, even if never explicitly rehearsed, must be the reason why the believer continues to accept the belief and to appeal to it for further purposes. A full account of coherentist observation would have to spell out exactly what this requirement amounts to and how it can be satisfied.

Third, the bare possibility of coherentist observation seems insufficient to accommodate the role that observation plays in our cognitive lives. Given the convictions that observation is not only possible but pervasive and that an appeal to observational evidence, whether direct or indirect, is essential for the justification of at least contingent beliefs about the world, an intuitively adequate coherence theory must somehow *require* and not just allow that a substantial observational element should be present in any justified system that includes such contingent beliefs. A view that insisted on such a requirement would thereby depart from a pure coherence theory, but might still avoid foundationalism if the coherentist account of observation is otherwise successful. (Such a requirement is relevant to several of the objections examined below.)

5 The standard objections

In considering objections to coherence theories, we may begin with the three that are historically most standard and familiar. The first of these is what is commonly referred to as 'the isolation problem' or 'the input objection': an account of justification that appeals entirely to coherence within a system of beliefs seems to have the consequence that the justificatory status of the beliefs in the system will not depend in any way on the relation of the system to the world that it purports to describe, or on any sort of information derived from that world. This would seem to mean in turn that the truth of the component beliefs, if they happened to be true, could only be an accident, and thus that there is no reason to think that they are true and so no epistemic justification. The coherentist account of observation sketched above, if it can be successfully fleshed out, provides the beginning of an answer to this objection by showing how observational beliefs that are apparently generated by the world might none the less be given a coherentist justification. In this way, a coherent system that involves a putatively observational component will at least seem from the inside to have input from the world and thus not to be isolated. Whether this seeming is likely to be veridical will depend, however, on the more general issue, discussed below, of whether and why coherentist justification should be regarded as conducive to finding the truth.

The second familiar objection, already briefly alluded to earlier, is what may be called the alternative coherent systems objection: even given a relatively strong account of coherence, there will still be indefinitely many different possible systems of beliefs, each of which is as internally coherent as the others, and so all of which will be equally justified on a coherentist view – surely an absurd result. The response to this objection also depends crucially on the idea of observation. If, as suggested earlier, it will be a requirement for justification in an adequate coherence theory that there be a substantial observational component (that is, a substantial proportion of cognitively spontaneous beliefs that the system itself certifies as likely to be true and hence worthy of being accepted), then such alternative systems can no longer be freely invented and it is no longer obvious why they should be thought to exist. Only a system that is actually accepted and employed in cognitive practice can contain cognitively spontaneous beliefs and thus satisfy the requirement for observation. There is no way to guarantee that the acceptance of such beliefs will not lead quickly to incoherence in an arbitrarily devised system, even if it is initially coherent. (As this suggests, it is coherence over a period of time and not just at a moment that is ultimately the basis for justification in all coherence theories that have been seriously advocated.)

The third of the standard objections is in effect a challenge to the coherentist to give a reason for thinking that adopting beliefs on the basis of coherentist justification is likely to lead to believing the truth. Different coherentists give very different responses to this crucial question, each problematic in its own way. These can only be briefly sketched here. (1) The absolute idealists in effect solve the problem by adopting a coherence theory of truth as well, thus reducing the gap between coherentist justification and truth (though only Blanshard is very explicit about this strategy). On such a view, truth is essentially identified with long-run justification, making it relatively easy to argue that seeking justified beliefs is likely to lead eventually to finding

true ones – but at the significant cost of adopting an extremely implausible conception of truth. (2) Rescher attempts to give a pragmatic argument to the effect that the practical success which results from the employment of the coherent system makes it likely that the beliefs of the system are at least approximately true (in the sense of corresponding to independent reality). Unfortunately, however, the need for justification for the claims of practical success, which must presumably also be coherentist in character, threatens the project with vicious circularity. (3) BonJour (1985) attempts to give an a priori 'metajustificatory argument', relying on a rationalist and foundationalist conception of a priori knowledge, for the conclusion that a system of beliefs that remains coherent over the relatively long run, while receiving apparent observational input, is likely to be approximately true (again in the correspondence sense of truth). The main reason offered is that only approximate truth could explain continued coherence in the face of new observations. In addition to defending the general account of a priori justification presupposed, such an approach must also claim that sceptical explanations of one's beliefs (for example their being produced by a Cartesian demon), are a priori less likely than the preferred explanation of correspondence with reality, a claim that many have found highly implausible. (4) Lehrer's approach is to construct alternative conceptions of justification that involve the hypothetical replacement of erroneous beliefs in a person's system of beliefs with their corrected alternatives, and then require that the person's initially justified beliefs remain justified after such replacements in order for such beliefs to constitute knowledge. The main difficulty here is that such an approach seems to concede that 'personal justification' – the sort of justification which exists before the hypothetical replacements – is not in itself conducive to finding the truth, even though such personal justification is the only sort that the believer is in general ever actually aware of.

6 The problem of access

In addition to the foregoing objections, there are a number of further problems with which an adequate coherence theory would have to deal. Perhaps the most urgent of these is that of whether coherentist justification is accessible to the believer in the way that it must be if an internalist position is to result. Assuming for the moment, as is the case with all the positions discussed here, that coherentist justification is taken to require coherence with the believer's entire system of beliefs, then there are three aspects to this problem: (1) whether the believer has adequate access to their system of beliefs; (2) whether the believer has an adequate grasp of the concept of coherence; and (3) whether the believer is able to apply the concept of coherence to their system of beliefs in a way that will yield a definite assessment. All these aspects pose serious problems, and (3) in particular is anything but trivial, even given satisfactory solutions to (1) and (2). But (1) is the most difficult and will accordingly be the main focus here.

A believer's access to their own system of beliefs is in fact seriously problematic in two quite different ways. First, there is the problem of the epistemological status of the result of such access if it were achieved, which we may think of as a reflective meta-belief describing the entire contents of the system. Such a meta-belief would be clearly contingent and empirical and hence one that on any coherence theory of the sort under consideration here ought to be itself justified by appeal to coherence. But since any coherentist justification that is to be accessible to the believer must appeal to such a meta-belief in order to characterize the system of beliefs with which the belief to be justified must cohere, a coherentist justification of that meta-belief itself appears to be totally and irrevocably circular (and no appeal to non-linear justification will help here, since what is being explained is how the very sort of non-linear justification advocated by the coherentist is possible).

The most explicit discussion of this issue is given by BonJour (1985), who responds by invoking what he calls 'the Doxastic Presumption'. The idea is that coherentist justification must *presume* that the believer's grasp of their overall system of beliefs is at least approximately correct (small corrections being possible by appeal to coherence). This has the consequence that the resulting justification is contingent upon the presumed correctness of this grasp, and hence that there is no possible answer on the part of a coherence theory to the specific variety of scepticism that questions whether this presumption is indeed correct. This has seemed to many to be a very drastic result, but it is unclear what the alternative might be, so long as foundationalism is eschewed.

Even if the foregoing issue were resolved in a satisfactory way, there is still the second aspect of the present problem: the quite sticky issue of whether ordinary believers ever in fact possess or could possess anything like the reflective grasp of the entire contents of their systems of beliefs that a coherence theory seems to require. On this issue, it seems likely that a coherence theory will have to concede that ordinary cases of justification are at best only an approximation, and perhaps a fairly distant one, to the ideal justification that a coherence theory portrays.

One further problem is worth a brief mention. If, as is almost always the case, a coherence theory appeals to coherence over the relatively long run, then the issue arises of how the memory beliefs upon which any access to the fact of continued coherence must seemingly rely, are themselves to be justified. Many philosophers have offered coherence theories of the justification of memory beliefs, but such a view is again threatened with vicious circularity if the only reason for thinking that coherentist justification is conductive to truth – and so that the memory beliefs in particular are true – relies on coherence over time, and so on those very memory beliefs themselves.

KNOWLEDGE, CONCEPT OF

Introduction

The branch of philosophy concerned with the nature and extent of human knowledge is called epistemology (from the Greek *epistēmē* meaning knowledge, and *logos* meaning theory). Knowledge seems to come in many varieties: we know people, places and things; we know how to perform tasks; we know facts. Factual knowledge has been the central focus of epistemology.

We can know a fact only if we have a true belief about it. However, since only some true beliefs are knowledge (consider, for example, a lucky guess), the central question asked by epistemologists is 'What converts mere true belief into knowledge?'. There are many, and often conflicting, answers to this question. The primary traditional answer has been that our true beliefs must be based upon sufficiently good reasons in order to be certifiable as knowledge. Foundationalists have held that the structure of reasons is such that our reasons ultimately rest upon basic reasons that have no further reasons supporting them. Coherentists have argued that there are no foundational reasons. Rather, they argue that our beliefs are mutually supporting.

In addition to the constraints upon the overall structure of reasons, epistemologists have proposed various general principles governing reasons. For example, it seems that if my reasons are adequate to affirm some fact, those reasons should be adequate to eliminate other incompatible hypotheses. This initially plausible principle appears to lead directly to some deep puzzles and, perhaps, even to scepticism. Indeed, many of the principles that seem initially plausible lead to various unexpected and unwelcome conclusions.

Alternatives to the primary traditional answer to the central epistemic question have been developed, in part because of the supposed failures of traditional epistemology. These alternative views claim that it is something other than good reasons which distinguishes (mere) true beliefs from knowledge. Reliabilists claim that a true belief produced by a sufficiently reliable process is knowledge. Good reasoning is but one of the many ways in which beliefs can be reliably produced. The issue of whether the objections to traditional epistemology are valid or whether the proposed substitutes are better remains unresolved.

1 The varieties of knowledge

Knowledge comes in many varieties. I can know *how* to adjust a carburettor. I can know a person. I can know *that* mixing bleach and ammonia is dangerous. In the first case, I possess a skill. In the second, I am acquainted with someone. In the third, I know a fact. Epistemologists have differed on the relationships between these types of knowledge. On the one hand, it could be held that knowing a person (place or thing) should be construed as nothing more (or less) than knowing certain facts about that someone and possessing the skill of being

able to distinguish that person from other objects. On the other hand, it has been held that knowing facts depends upon being acquainted with particular objects. Whether the reduction of one form of knowledge to another is ultimately successful is an area of contention among epistemologists.

Nevertheless, it is knowledge of facts, so-called *propositional knowledge*, as opposed to knowledge by acquaintance or the possession of skills, that has been the central concern of epistemologists. The central question can be put this way: which beliefs of mine are to be counted as knowledge? This question presupposes that knowledge is a species of belief, but some might think that knowledge and belief are mutually exclusive: for example, we say such things as 'I do not *believe* that; I *know* it'. But we also say such things as 'I am not *happy*; I am *ecstatic*'. A suggested paraphrase of this expression seems to capture what is meant without denying the obviously true claim that ecstasy is a form of happiness. The paraphrase is: I am not *merely* happy, I am ecstatic. The parallel is: I do not merely believe it; I know it. Thus, this type of linguistic evidence does not support the suggestion that belief and knowledge are mutually exclusive. In general, epistemologists have held that propositional knowledge is a species of belief.

2 Propositional knowledge is not mere true belief

Propositional knowledge is a species of belief; but which beliefs are knowledge? The first thing to note is that a belief must be true in order for it to count as knowledge. But that is obviously not enough. First, true beliefs can be based upon faulty reasoning. Suppose that I believe that smoking is a leading cause of fatal lung cancer because I infer it from the fact that I know two smokers who died of lung cancer. The generalization is true, but my evidence is too meagre for my belief to count as knowledge. Second, true beliefs can be based on false beliefs. Modifying an example used by Bertrand Russell, suppose that I believe truly that the last name of the President of the United States in 1996 begins with a 'C'. Also suppose this belief is based upon the false belief that the President is Winston Churchill. My true belief that the President's name begins with a 'C' is not knowledge because it is based on a false belief.

Third, even some true beliefs resulting from good reasoning based upon true beliefs are not knowledge. Suppose that I believe (truly) that my neighbours are at home. My belief is based upon good reasoning from my true belief that I see lights on and that, in the past, the lights have been on only when they were at home. But suppose further that this time the lights were turned on by a guest and that my neighbours had just entered the house and would not have had time to turn on the lights. In this case, I fail to know that my neighbours are home. So, the central question becomes: what must be added to true belief to convert it into knowledge?

3 Warrant

The property, whatever it is, that, if added to true belief converts it into knowledge, we may refer to as 'warrant'. Knowledge, then, is true, warranted, belief. But simply to name the missing property does not bring us closer to understanding it and we must be careful not to think of 'warrant' as a sophisticated synonym for 'justified'. Let us say that a belief is *justified* just in case we are entitled to hold it on the basis of suitable reasons available to us. In the neighbour/lights case mentioned above, we have already seen that justification is not sufficient for warrant. Whether it is even necessary will be important in the discussion that follows, especially in §6.

Given the great variety of approaches to an account of warrant, is there any common, underlying starting point embraced by epistemologists? Yes: a warranted belief is one that is not held on the basis of mere cognitive luck. Plato appeals to that intuition in the *Theaetetus*; Aristotle's account of the transition from ignorance of the first principles in science to knowledge of them in the *Posterior Analytics* is designed to demonstrate that there are reliable cognitive mechanisms whose output is not the result of chance; Descartes proposes methods for acquiring beliefs that would (he thinks) necessarily lead to truth; Locke suggests that even if persons arrive at a true belief by accident, they are not thereby free from criticism.

Let us start with the assumption that a proposition is known just in case it is not an accident, from the cognitive point of view, that it is both believed and true. Hence the task becomes one of developing an account of warrant that accurately portrays what it is that makes a belief non-accidentally true from the cognitive point of view.

4 Foundationalism and coherentism

There are two main, traditional approaches to the account of justification: foundationalism and coherentism. Both are *normative* views about rules in virtue of which propositions *ought* to be accepted or *ought* to be rejected or *ought* to be suspended (see Knowledge and justification, coherence theory of; Foundationalism). In order to characterize these approaches, recall how the

ancient Pyrrhonian Sceptics divided the possible structures of reasons that provide a basis for accepting a belief (see EPISTEMOLOGY, HISTORY OF; PYRRHONISM). Suppose you hold a belief and offer another belief as the reason for the first – for example, suppose you believe that Ford cars are generally less expensive than BMWs. Your reason could be your belief that you were told so by a reliable person. An obvious question arises: what is your basis for believing that the person is reliable? You could answer with another reason and that reason could, itself, be supported by a further reason, and so on.

This process of providing reasons for your beliefs can have only three possible structures:

Foundationalism: The process of giving reasons could be such that not every reason is supported by another reason because there are *basic reasons* which have no need of further reasons supporting them.

Coherentism: The process of giving reasons could have no reason that is not supported by another reason, but there is not an infinite number of reasons. Thus, beliefs are mutually supporting.

Infinitism: The process of giving reasons could have no reason that is not supported by another reason, but there is an infinite number of reasons.

Foundationalism and coherentism have both been developed and defended, and there are well-known objections to each view. In contrast, the *prima facie* objections to infinitism have seemed so overwhelming that it has not been investigated carefully. Infinitism *seems* to require that a person should have an infinite number of beliefs (which *seems* on its face to be false). In addition, it *seems* to lead inevitably to the conclusion that no belief could ever be justified, since the process of justification would never come to an end.

The standard objections to foundationalism are several. First, as the Pyrrhonians would point out, there must be a distinction between what makes a belief *properly* basic and what makes it simply one for which no other reason is, in fact, given. Otherwise, the offered 'basic' reason is arbitrary. But if there is some further reason for thinking that an offered reason is not arbitrary, then there is a reason for accepting it, and the offered reason is, thereby, not basic. Hence, there can be no foundational propositions.

Second, some preferred candidates for properly basic reasons seem not to be properly basic on closer inspection. Consider perceptual judgments – the source of most of our knowledge of the external world according to many philosophers (see EMPIRICISM; A POSTERIORI). A reason for believing that there is a tree before me is that I see a tree before me. But the latter proposition does not appear to be properly basic because one could be required to explain what it is about what is seen that leads one to believe that it is a *tree* that one sees (as opposed to an illusion). Thus, some foundationalists have retreated to sensation-beliefs (so-called sense-data propositions) as their candidates for properly basic beliefs: for example, 'I seem to see a green, brown, tallish object' (see AYER, A.J.; MOORE, G.E.). But although these propositions might seem to be properly basic, there are notorious problems with the sense-data view (see SENSE-DATA). First, the proffered basic beliefs seem to be too meagre to provide a sufficient basis for the rich scope of things we seem to know. For example, how can my knowledge that objects persist when not being perceived be traced to particular sense-data? Second, it appears that our knowledge of the way in which to characterize our sensations (private sensations accessible only to the individual having them) depends upon our knowledge of public objects (see CRITERIA; WITTGENSTEIN, L.J.J.). How could we know, for example, that we have a throbbing pain without first recognizing what it is for a public object (say, a muscle) to be throbbing?

Foundationalists have developed answers to these objections in part by liberalizing the requirements either for being properly basic or for being an acceptable pattern of inference from the foundational propositions to the non-foundational ones (see INFERENCE TO THE BEST EXPLANATION). For example, *contextualist* accounts of knowledge have been developed that hold that a proposition is properly basic just in case it is accepted by the relevant community of putative knowers. In a discussion with a friend I could offer 'I read it in the newspaper' as my reason for believing another moon of Jupiter had been discovered. I would not need further reasons for believing that I read it. In contrast, at a convention of astronomers that reason would not be accepted. Hence, contextualists claim, what counts as a basic reason is context-dependent.

There are two obvious responses to contextualism. The first is that it might be an accurate description of some aspects of our epistemic practices, but the fundamental Pyrrhonian question remains: what distinguishes a properly basic proposition from one that is merely offered and accepted by a community of putative knowers? The issue concerns what beliefs, if any, *ought* to be offered and accepted without further reasons. The question is not what beliefs *are* offered and accepted without further reason. The second response is a corollary of the first. Knowledge seems to be a highly prized state of belief (as PLATO put it). But, if the

contextualists were right, I would gain knowledge by joining a community of rather epistemically gullible and permissive folk. That hardly seems right! (See CONTEXTUALISM, EPISTEMOLOGICAL.)

In sum, it remains a subject of dispute among epistemologists whether the stock of purported foundational propositions can be made sufficiently rich and abundant without including too many that clearly require evidential support, or whether the patterns of inferences can be liberalized sufficiently without allowing patterns that are not sufficiently truth-conducive.

The historical rival of foundationalism is coherentism. Coherentists deny that there are basic reasons and claim that all propositions derive their warrant, at least in part, from other propositions. The fundamental objection is this: Typically, we recognize that arguing in a circle is not an acceptable pattern of inference, so what makes it acceptable in some cases? Suppose I believe that apples contain vitamin C, at least in part because I believe that fruits contain vitamin C. I would surely be appropriately accused of circular reasoning if I believed, in part, that fruits contain vitamin C because apples do.

Coherentists would be quick to point out that they are not really suggesting that one should argue in a circle. Rather, they would point to the fact that our beliefs come in bunches with a web-like structure (see QUINE, W.V.). They are ‘mutually supporting’ just as the poles in a tepee are mutually supporting. A belief is warranted just in case it is a member of a set of coherent beliefs.

But whether these colourful analogies answer the basic objection is not clear. Presumably, circular reasoning is not acceptable because although it might be the case that if you believe b_1 it might be reasonable to believe b_2, and if you believe b_2 it might be reasonable to also believe b_1, their mutual support gives you no reason for believing them both. Thus, the fundamental question is this: What makes one total set of coherent beliefs, say T_1, any more acceptable than an alternative total set of coherent beliefs, say T_2?

The Pyrrhonian Sceptics would point out that coherentists either have an answer for that question or they do not. If they do, then they seem to have abandoned their central view, since there now seems to be a reason for adopting the set of beliefs, T_1, that is not one of the beliefs in T_1. Indeed, if they provide an answer, they have embraced foundationalism. If they do not have an answer, then it seems that adopting T_1 is arbitrary. Coherentists have attempted to answer this objection by giving a ‘meta-justification’ for thinking that certain kinds of coherent belief systems are likely to contain true members. Indeed, some have argued that coherent beliefs are, by their very nature, likely to be true (see DAVIDSON, D.). But whether that strategy will suffice to answer the objections remains an open question in epistemology.

5 Defeasibility theories

A basic objection to the foundationalist’s and coherentist’s accounts of justification is that neither seems to be able to show that a true belief which satisfied their accounts would be non-accidentally true. First, as the neighbour/lights case showed, a true belief could be fully justified on their accounts, but not be knowledge. Second, as the Pyrrhonians pointed out, either the beliefs seem to rest upon arbitrary foundations or they seem to be only one of many, equally coherent sets of beliefs. The defeasibility theory was developed, in part, to address these issues. It holds, roughly, that it is not only the evidence that one possesses that makes a belief warranted; it is equally important that there is no defeating evidence that one does not possess. That is, in order for a belief to be warranted it must not only be justified (in the sense required by either the foundationalists or the coherentists) but its justification must be such that there is no truth which, if added to the reasons that justify the belief, is such that the belief would no longer be justified.

The defeasibility theory can explain why it is not a cognitive accident that the warranted belief is true. If any of the important supporting reasons (those that if removed would destroy the justification) were false, then adding the denial of those reasons (in other words, adding the truth) to one’s beliefs would undermine the justification. In addition, if there is evidence that one does not possess such that it makes it an accident that the belief is true, the propositions describing that evidence would undercut the justification.

A well-known case will help to illustrate this (see GETTIER PROBLEM). Suppose that I know Tom Grabit well and I see what appears to be Tom stealing a library book: I come to believe that Tom stole a library book. And, let us suppose that Tom did indeed steal the book. Foundationalists and coherentists could deploy their accounts in order to show that the belief is justified. Nevertheless, suppose that, unknown to me, Tom has an identical twin, John, who is a kleptomaniac and was in the library on the day in question and stole a copy of the same book. Even though I arrived at a true belief as a result of good reasoning based upon true propositions, I do not know that Tom stole the book since it is accidental, from the cognitive point of view, that I arrived at the truth. I could just as easily have based my belief on having seen John stealing the book.

The defeasibility theorists would point out that the belief that Tom stole the book is defeated; if the true proposition describing John were added to my beliefs, I would no longer be justified in believing Tom stole the book. In general, the defeasibility theory can rule out accidentally true beliefs as warranted because those beliefs would not be able to stand up to the truth.

Nevertheless, the defeasibility theory has its problems. The primary one is that it seems to exclude too much from what we know. Returning to the Grabit Case, suppose that everything is as it was except that Tom does not have a twin but that Tom's mother sincerely avows the claims about John. Now, there is a true proposition (Tom's mother has said sincerely that Tom has an identical twin, John) that defeats the original justification. Hence the belief that Tom stole the book would be defeated. But if Tom's mother were demented and there never was a twin, it seems that I knew all along that Tom stole the book.

Defeasibility theorists have tried to answer this objection by suggesting ways to distinguish between so-called misleading defeaters (for example, Mrs Grabit sincerely avows that Tom has an identical twin, John) and genuine ones (for example, Tom has an identical twin, John), but there is no agreement among epistemologists that any of these suggestions has succeeded in correctly capturing the distinction between genuine and misleading defeaters.

6 Externalism

Partly in response to the difficulties with foundationalism and coherentism even as supplemented by the defeasibility theory, epistemologists have developed a variety of alternative accounts of warrant. They have been called 'externalistic' because their accounts of warrant focus on features of the world other than the knower's reasons for belief. Two important ones are the causal theory and the reliabilist theory.

In their purest forms, these accounts begin with the view that knowledge, and hence warrant, does not require justification. The foundationalists had already conceded that there are no reasons for properly basic beliefs. This seemed to create a problem for foundationalism only because it was assumed that all beliefs needed to be justified and the 'basic' reasons appeared to be arbitrary. But drop the requirement that beliefs need to be justified in order to be warranted, and this problem immediately disappears.

Roughly, the causal theory of warrant holds that a belief is warranted if and only if the state of affairs represented in the belief is appropriately causally related to the belief. For example, suppose I come to believe that there is a bird in a tree as a causal consequence of seeing the bird in the tree. Sometimes the causal connection is more complex; but this direct type of causal connection between the belief and what it represents will suffice for our purposes.

This theory is initially appealing because it appears to satisfy the basic requirement that a warranted belief be non-accidentally true since the state of affairs represented in the belief is a cause of my belief. However, it is easily seen to be both too weak and too strong; and there seem to be some deep problems with it as a general account of warrant. It is too weak because it would count some true beliefs as warranted that clearly are not known. Recall the Grabit case. My belief that I see Tom stealing the book is caused by Tom's stealing the book, but if he has an identical twin, I do not know that Tom stole the book. It is too strong because there seem to be many beliefs that count as knowledge which can not be appropriately *causally* related to what they represent. Suppose I know that there is no elephant smaller than a kitten: what possible *causal* connection could there be between there being no elephant smaller than a kitten and my belief? In addition, potential difficulties arise about knowledge of a priori propositions (such as 2 + 2 = 4) and counterfactuals (such as, if it were raining today, we would have called off the picnic). It looks as though there is no possible way to produce a causal connection between my belief and what is represented in the belief – at least as 'cause' is usually understood (see A PRIORI).

Nevertheless, a basic tenet of the causal theory might still be correct: Not all beliefs need to be based on reasons in order to count as knowledge. The reliabilist theory of warrant can be seen as the successor of the causal theory. Instead of requiring an appropriate causal connection between the states of affairs represented in the belief and the belief itself, a typical form of reliabilism holds that a belief is warranted just in case the process resulting in the belief produces true beliefs sufficiently often.

Thus, the non-accidental nature of the true belief receives a very straightforward analysis. The belief is non-accidentally true because the process that produces the belief produces true beliefs sufficiently often. This view has many advantages over the causal theory. My belief that elephants are larger than kittens need not be caused by that state of affairs. All that is required is that the process by which I come to believe that proposition typically (often enough) results in true beliefs. A priori or counterfactual propositions present no problem since there could be reliable processes that produce those beliefs.

Nevertheless, there are problems confronting this view. Suppose that you require that the process

should produce true beliefs on 100 per cent of the occasions on which it arises. That is a very stringent condition; but it is not stringent enough! For if the belief that Tom Grabit stole a book arises only once in the history of the world – the time I saw him stealing the book – the actual process produced a true belief 100 per cent of the times it arose; but it is not knowledge. The obvious move for the reliabilist is not only to include the actual occasions when the particular belief is produced but rather to consider whether the type of process that produced this belief would produce true beliefs of this type sufficiently often. But correctly characterizing those types has not proved easy. Is the type of belief one in which Tom is involved? Or identical twins? Or libraries? That seems too narrow. Is the type of process one in which there is first a perception and then some inferences? That seems too broad. It remains an open question whether reliabilism can produce an acceptable account of the types of processes and the types of beliefs.

Finally, there is one further objection that some epistemologists have brought against reliabilism. Perhaps it is best illustrated in a case presented by Keith Lehrer in his *Theory of Knowledge* (1990) that can be summarized as follows: a certain Mr Truetemp has a thermometer-with-temperature-belief-generator implanted in his head so that within certain ranges of temperatures he has perfectly reliable temperature beliefs. When it is 50 degrees, he comes to believe that it is 50 degrees. When it is not 50 degrees, he does not come to believe that it is 50 degrees. He holds these beliefs without knowing why he does.

Such beliefs would satisfy all of the requirements suggested by the reliabilists, but many epistemologists would hold that although Mr Truetemp has true beliefs and they are not accidentally true because his thermometer-with-temperature-belief-generator is reliable, they are accidentally true *from the cognitive point of view*, as he has no reasons at all for his beliefs. Indeed, some would say that what Mr Truetemp possesses is a skill (of telling the temperature) and not propositional knowledge at all.

Here we can detect a fundamental clash of intuitions. The reliabilists would hold that Mr Truetemp does know; the traditional normativists would hold that he does not. There appears to be no way to satisfy both. But this much seems clear: There are some situations in which the steps in the process that brings about a belief include the holding of reasons. In those cases in which there is no automatic true-belief-generator (as in the Truetemp case) and in which we must rely upon our reasoning to arrive at a belief, the questions asked by the traditional normativists are crucial: what must the structure of our reasons be so as to make a true belief acceptable? Are there foundational reasons? Can mutually supporting reasons be offered without begging the question? (Could reasons be infinite in number?) And need those reasons be such that they are not undermined by the truth, as the defeasibility theorists would hold? At least in some cases, it seems that normative standards for belief-acquisition apply and their satisfaction will determine whether a belief ought to be accepted. Thus, it appears that an evaluation of the conditions under which beliefs ought to be accepted, denied or suspended is inescapable (see Internalism and externalism in epistemology; Justification, epistemic).

7 Epistemic principles

Epistemic principles describe the normative epistemic status of propositions under varying conditions. It is generally agreed that if a person, *S*, is justified in believing any proposition, *x*, then *S* is not at the same time justified in believing that not-*x*. Foundationalists and coherentists alike can, and typically do, accept this principle. Other principles are more controversial. They are intuitively plausible but they seem to provide a basis for scepticism and for some deep epistemic puzzles. Here are three of the more interesting principles.

Conjunction Principle (CON-P): If *S* is justified in believing that *x*, and *S* is justified in believing that *y*, then *S* is justified in believing that (*x* and *y*).

Closure Principle (CLO-P): If *S* is justified in believing *x*, and *x* entails *y*, then *S* is justified in believing that *y*.

Evidence Transfer Principle (ET-P): If there is some evidence, *e*, that justifies *S* in believing that *x*, and *x* entails *y*, then *e* justifies *S* in believing that *y*.

In each principle and with suitable grammatical modifications 'justified' could be replaced by other epistemic terms, such as 'reasonable', 'plausible', 'evident', 'certain'. Furthermore, each principle is designed to capture a basis upon which a positive normative epistemic status of a proposition can be transferred to another proposition. As a corollary, '*S* is justified in believing *x*' is not taken to entail '*S* does believe that *x*, justifiably'. For *S* may not form the belief because of a failure to see the connection between the propositions. Finally, with regard to CLO-P and ET-P, since a tautology is entailed by every proposition, the entailment must be restricted to some form of relevant entailment and/or the range of propositions must be restricted to contingent ones (see Relevance logic and entailment). Other restrictions are no doubt necessary;

but these three seemingly intuitive principles have been challenged at their core.

It is important to see some of the relationships between these principles. CLO-P does not entail CON-P since the CLO-P is about *one* proposition that *S* is justified in believing, not *sets* of propositions. In addition, CLO-P does not entail ET-P because CLO-P does not require that it is the *very same evidence*, *e*, that *S* has for *x* that justifies *y* for *S*. Thus, one can accept CLO-P without accepting either of the other principles.

8 The epistemic principles and scepticism

Scepticism – the view that we lack knowledge in those areas commonly thought to be within our ken – comes in many varieties. The most extreme view is global scepticism. It holds that we have very little, if any, knowledge. That view seems preposterous at first glance. Indeed, some epistemologists think that any theory that leads to global scepticism should, *ipso facto*, be rejected (see COMMONSENSISM; SCEPTICISM). Yet there are many arguments for global scepticism that are difficult to answer. In addition, more modest forms of scepticism about particular subject matters (for example, other minds or the future) have been developed. But since the more modest sceptics employ strategies similar to those employed by the global sceptics, I here consider only the most extreme form of scepticism – global scepticism (see OTHER MINDS).

We have already seen the basis for one such argument for global scepticism that can be gleaned from the Pyrrhonians, namely:

(1) All knowledge requires having reasons that are neither arbitrary nor question-begging nor infinitely many.

(2) The only structures for reasons are such that reasons are either arbitrary (foundationalism), question-begging (coherentism) or infinitely many (infinitism).

Therefore, there is no knowledge.

There are at least four possible responses to this argument: (1) the foundational, basic propositions are not arbitrary; (2) coherentism does not necessarily lead to question-begging arguments; (3) requiring infinitely many reasons for a belief does not entail that a belief cannot be justified; (4) not all knowledge entails having reasons. All but (3) have been systematically developed by epistemologists.

Pyrrhonism does not rely directly upon the epistemic principles discussed in the preceding section. But there are other important forms of scepticism that do. Consider this argument that can be traced to Descartes (see DESCARTES, R. §4):

(1) If I am justified in believing that there is a table before me, then I am justified in believing that I am not in one of the sceptical scenarios (evil demon worlds, for example) in which there is no table but it appears just as though there were one.

(2) I am never justified in believing that I am not in one of the sceptical scenarios in which there is no table but it appears just as though there were one.

Therefore, I am never justified in believing that there is a table before me.

Premise 1 is a clear instance of CLO-P. Since the argument is valid (if the premises are true, the conclusion must be true), there are only three plausible responses: (1) CLO-P is false; (2) the second premise is false; (3) the argument begs the question. Responses (1) and (2) are relatively easy to envisage; the third is not so obvious. Roughly, the argument goes as follows: since one of the potentially available grounds for my being justified in believing that I am not in a sceptical scenario is any proposition that entails that I am not in such a scenario, every good argument for the second premise would have to establish that I am not justified in believing that there is a table before me. But that, of course, is the very conclusion.

It is important to note that there is an apparently similar argument for scepticism employing the stronger epistemic principle, ET-P.

(1) If the evidence, *e*, that I have for believing that there is a table before me is adequate to justify that belief, then it is adequate to justify the belief that I am not in one of the sceptical scenarios.

(2) The evidence, *e*, is not adequate to justify that I am not in one of the sceptical scenarios.

Therefore, the evidence, *e*, is not adequate to justify that there is a table before me.

Of course, it is open to epistemologists to deny ET-P. Since one can deny ET-P without abandoning CLO-P (because CLO-P does not entail ET-P), that certainly seems to be a strategy worth considering. The discussion in the next section provides additional reasons for considering that strategy.

9 The epistemic principles and some paradoxes

There are many epistemic paradoxes (see PARADOXES, EPISTEMIC). I here consider two in order to show how they depend upon some of the epistemic principles considered earlier.

The Lottery Paradox: Suppose that enough tickets (say n tickets) have been sold in a fair lottery for you to be justified in believing that the one ticket you bought will not win. In fact, you are justified in believing about each ticket that it will not win. Thus, you are justified in believing the following individual propositions: t_1 will not win. t_2 will not win. t_3 will not win ... t_n will not win.

Now if the conjunction principle is correct, you can conjoin them, ending up with the obviously false but apparently justified proposition that no ticket will win. So, it seems that you are in the awkward position of being justified in believing each of a series of propositions individually, but not being justified in believing that they are all true. Some philosophers have thought that this seemingly awkward position is not so bad after all, since there is no outright contradiction among any of our beliefs as long as the conjunction principle is rejected. But others have thought that making it rational to hold, knowingly, a set of inconsistent beliefs is too high a price to pay.

Others have suggested that we are not actually justified in believing of any ticket that it will lose; rather what we are justified in believing is only that it is highly likely that it will lose. But the lottery can be made as large as one wants, so that any level of probability (below 1) is reached. Thus, this suggestion seems to rule out our being justified in believing any proposition with a probability of less than 1. That is a very high price to pay! There is no generally agreed-upon solution for handling the Lottery Paradox (see CONFIRMATION THEORY).

The Grue Paradox: The so-called 'Grue Paradox' was developed by Nelson Goodman and has been recast in many ways. Here is a way that emphasizes the role of ET-P:

> All of the very many emeralds examined up to the present moment, t_{now}, have been green. In fact, one would think that since we have examined so many of them, we are justified in believing that (G): all emeralds are green. But consider another proposition, namely that all emeralds examined up to t_{now} are green, but otherwise they are blue. Let us use 'grue' to stand for the property of being examined and green up to t_{now} but otherwise blue. It appears that the evidence which justifies us in believing that all emeralds are green does not justify us in believing that (N): no emerald is grue.

What are we to make of this version of the paradox? First, note that it depends upon ET-P. Although (1) our inductive evidence (the many examined green emeralds) justifies (G), and although (2) (G) does entail (N), the inductive evidence does not justify (N). In other words, this version of the paradox arises because the evidence does not transfer as the principle would require. Second, note that CLO-P is not threatened by this paradox since it is the evidence for (G) that is inadequate for (N). (The issue is not whether we are justified in believing (N) whenever we are justified in believing that (G).)

But if ET-P were not valid, then the sting of this version of the paradox can be pulled. Recall the original Grabit case. In that case, I had adequate evidence for being justified in believing that Tom stole the book, that is, the person stealing the book looked just like Tom. It seems clear that this evidence is not adequate to justify the proposition that it was not Tom's identical twin who stole the book. If it were the twin, things would appear to be just as they did appear to be. But this tends to show that we do not typically impose ET-P on our evidence.

There are other versions of the Grue Paradox that do not make explicit use of ET-P. For example, since 'all emeralds are green' and 'all emeralds are grue' are alternative hypotheses, it seems paradoxical that the very same evidence that justifies believing the first alternative also seems to support the second. But perhaps, like the version considered above, this apparent paradox rests on a mistaken intuition. Consider the Grabit Case once again. Here, the evidence which justifies the belief that Tom is the thief would also support the claim that Tom's identical twin stole the book. To generalize further, consider any hypothesis, say h, that is justified by some evidence that does not entail h. It is always possible to formulate an alternative hypothesis that is supported by that very evidence, namely (not-h, but it appears just as though h because of...). Thus, an intuitively plausible epistemic principle similar to ET-P might be invalid. That principle is: if there is some evidence, e, that justifies S in believing that x, and x is an alternative hypothesis to y, then e does not support y.

To sum up, if ET-P and similar epistemic principles do not accurately capture our normative epistemic practices and if the argument for scepticism that depends upon CLO-P begs the question, then the sting of Cartesian scepticism (considered in the previous section) is numbed and the Grue Paradox can be addressed. But those are big 'ifs', and the issue remains open (see INDUCTION, EPISTEMIC ISSUES IN).

10 Some challenges to traditional epistemology

A traditional question asked by epistemologists is 'what ought we to believe?' Typically, the answer is given by (1) describing the types of reasons that contribute to warranting a belief, and (2) developing a set of necessary and sufficient conditions for

knowledge in which the types of reasons depicted in (1) play a prominent role. But there are many challenges to this answer.

We have already seen the challenge developed by the causal theorists and the reliabilists. Roughly, they hold that our beliefs need not be the result of proper reasoning to be counted as knowledge. Sufficiently reliable belief-acquisition methods are all that is required. Indeed, some have held that epistemology, when done correctly, is a branch of psychology because the primary issue is the study of reliable belief-acquisition methods. This programme has often been referred to as 'naturalized epistemology' and, in one form, its basic tenet is there are no a priori knowable epistemic principles (see NATURALIZED EPISTEMOLOGY; QUINE, W.V.).

Another challenge to traditional epistemology comes from 'virtue epistemology', which makes the primary object of epistemic evaluation traits of persons rather than properties of beliefs or belief-forming processes. The virtue approach has been taken farthest by Linda Zagzebski, who proposes an epistemic theory modelled on virtue ethics and argues that such a theory permits the recovering of such neglected epistemic values as understanding and wisdom (see VIRTUE EPISTEMOLOGY).

A further type of challenge is that of Edward Craig. While allowing that the debate has been shaped by real features of the concept of knowledge, he rejects the project of analysing it in necessary and sufficient conditions. Instead, he tries to 'synthesize' the concept by deriving these features from a pragmatic hypothesis about its purpose, thus explaining the debate rather than joining it.

Even more radical challenges have been developed. First, some have argued that there is no unique method of acquiring and revising beliefs that ought to be employed by all people. Second, it has been argued that the proposed conditions of good reasoning (for example, objectivity and neutrality) tacitly aim at something other than truth. They are developed to prolong entrenched power (see FEMINIST EPISTEMOLOGY). Finally, it has been argued that successful belief acquisition occurs when the future can be adequately anticipated and controlled (see PRAGMATISM).

The defenders of traditional epistemology have two basic types of reply. First, they can examine the particular arguments developed by the critics to determine whether any one of them is sound. Second, they can point out that the critics will have to defend the reasonableness of their views by at least tacitly employing the very principles of good reasoning investigated by traditional epistemologists. Of course, this would not show that the critic's position is false, but it does at least illustrate the universality of the question 'what ought we to believe?'.

KNOWLEDGE, TACIT

Tacit knowledge is a form of implicit knowledge we rely on for both learning and acting. The term derives from the work of Michael Polanyi (1891–1976) whose critique of positivistic philosophy of science grew into a fully developed theory of knowledge. Polanyi believed that the 'scientific' account of knowledge as a fully explicit formalizable body of statements did not allow for an adequate account of discovery and growth. In his account of tacit knowledge, knowledge has an ineliminable subjective dimension: we know much more than we can tell. This notion of tacit knowing in science has been developed by Thomas Kuhn, has figured prominently in theoretical linguistics and has also been studied in psychology.

KOTARBIŃSKI, TADEUSZ (1886–1981)

Kotarbiński was one of the founders and main representatives of the Polish philosophical school known as the Lwów–Warsaw School and akin to, though independent of (and less radical than), the Vienna Circle. H was an anti-metaphysical, pro-scientific, rationalistic school of philosophy, which was very active and influential between the First and the Second World Wars.

Kotarbiński's programme for philosophy was a minimalistic and a practical one: he stressed the need to purify the field of philosophy of questions and concepts that lack factual content or logical coherence. According to him, the term 'philosophy' should be used, if at all, to denote only logic (understood as the philosophy of cognitive thought) and the philosophy of action, including moral philosophy. His numerous (more than 500) works are devoted to logic and philosophy of action in this broad sense. One of his main original ideas is the doctrine of reism or concretism, a special version of nominalism.

Kotarbiński was admired by several generations of his pupils for his unusual pedagogical gifts, his integrity and his moral courage.

B. STANOSZ

KRIPKE, SAUL AARON (1940–)

Saul Kripke is one of the most important and influential philosophers of the late twentieth century. He is also one of the leading mathematical logicians, having done seminal work in areas including modal logic, intuitionistic logic and set theory. Although much of his work in logic has philosophical significance, it will not be discussed here.

Kripke's main contributions fall in the areas of metaphysics, philosophy of language, epistemology, philosophy of mind and philosophy of logic and mathematics. He is particularly well known for his views on and discussions of the following topics: the concepts of necessity, identity and 'possible worlds'; 'essentialism' – the idea that things have significant essential properties; the question of what determines the referent of an ordinary proper name and the related question of whether such names have meanings; the relations among the concepts of necessity, analyticity, and the a priori; the concept of belief and its problems; the concept of truth and its problems; and scepticism, the idea of following a rule, and Ludwig Wittgenstein's 'private language argument'

MICHAEL JUBIEN

KRISTEVA, JULIA (1941–)

Born in Bulgaria, Kristeva entered the Parisian scene of avant-garde intellectuals in the 1960s. Her earliest work in linguistics was shaped by the post-Stalinist communism of eastern Europe, a political climate that exerts its influence on her entire corpus, even as she distanced herself from it, to embrace an increasingly psychoanalytic perspective. Dissatisfied with scientific models of language, conceived as a mere means of communicating preconceived ideas, where words simply function as isolated symbols that represent discrete concepts, Kristeva analyses language as a signifying process. As such, language is not a static and closed system of signs, but a mobile, fluid process that implicates bodily and vocal rhythms in the generation of symbolic meanings. In *La Révolution du language poétique* (1974) (*Revolution in Poetic Language*, 1984) Kristeva fuses linguistic insights with psychoanalytic inquiry as she presents two distinct yet interrelated aspects of the signifying process, the semiotic and the symbolic. The semiotic aspect of language is vocal, pre-verbal, rhythmic, kinetic and bodily. The symbolic aspect of language is social, cultural, and rule-governed. Focusing on the interplay between the semiotic and the symbolic, Kristeva is able to analyse literary and historical texts, works of art and cultural phenomena in a way that thematizes the complex relationship between materiality and representation.

TINA CHANTER

KUHN, THOMAS SAMUEL (1922–96)

The early 1960s saw substantial turmoil in the philosophy of science, then dominated by logical empiricism. Most important was the confrontation of the prevailing philosophical tradition with the history of science. Whereas the philosophy of science was mainly normatively oriented, that is it tried to delineate what good science should look like, historical studies seemed to indicate that the practice of science both past and present did not follow those prescriptions.

Thomas S. Kuhn was educated as a theoretical physicist but soon turned to the history and philosophy of science. In 1962, he published *The Structure of Scientific Revolutions* (*SSR*). This book was the single most important publication advancing the confrontation between the history and the philosophy of science; it is now a classic in science

studies. *SSR* was most influential not only in the discussion within philosophy but also in various other fields, especially the social sciences. The central concepts of *SSR*, like scientific revolution, paradigm shift and incommensurability, have been in the focus of philosophical discussion for many years, and the term 'paradigm' has even become a household word (although mostly not in Kuhn's intended sense). After *SSR*, Kuhn continued to develop his theory; apart from minor modifications it is mainly the explication of *SSR*'s more intricate philosophical topics, especially of incommensurability, which is characteristic of his later work.

PAUL HOYNINGEN-HUENE

KŪKAI (774–835)

Kūkai, also known by his posthumous honorific title Kōbō Daishi, was the founder of Japanese Shingon ('truth word' or 'mantra') Buddhism and is often considered the first comprehensive philosophical thinker in Japanese history. Building on the Buddhist esoteric tradition first developed in India and then in China, where Kūkai encountered it, he maintained that reality is a cosmic person, the Buddha Dainichi. Dainichi's cosmic thoughts, words and deeds form microcosmic configurations, resonances and patterns of change. By performing Shingon rituals, one can supposedly accord with the microcosmic constituents and know the foundational structures of reality that compose the sensory world in which we ordinarily live.

LA METTRIE, JULIEN OFFROY DE (1709–51)

La Mettrie is best known as the author of the eighteenth-century materialist manifesto, *L'Homme machine* (1747). His interest in philosophical issues grew out of his preoccupation with medicine, and he developed a tradition of medical materialism within the French Enlightenment. Born in St Malo, into the family of a prosperous textile merchant, La Mettrie pursued a medical career in Paris. He also studied for two years with the renowned Hermann Boerhaave in Leiden. After a brief period of medical practice, La Mettrie devoted his efforts to his translations and commentaries on Boerhaave's medical works. He also began to publish the works that made him a pariah to both the Faculty of Medicine of Paris and to the orthodox – that is, his medical satires and his first work of materialist philosophy, *L'Histoire naturelle de l'âme* (1745). Because of the outrage provoked by these works, he was exiled to Holland in 1745. But *L'Homme machine*, the text in which he applied his materialism thoroughly and explicitly to human beings, was too radical even for the unusually tolerant Dutch, and La Mettrie was forced to seek asylum at the court of Frederick the Great where he later died. His willingness to publish ideas his contemporaries considered too dangerous led the *philosophes* to repudiate him.

KATHLEEN WELLMAN

LABRIOLA, ANTONIO (1843–1904)

Antonio Labriola was the founder of Italian theoretical Marxism. Generally situated in the Marxism of the Second International, he was more questioning than others in that movement. He profoundly influenced the development of Italian thought, constantly challenging the influential idealism of Benedetto Croce and Giovanni Gentile. His attempt to maintain a place for human creativity within a deterministic Marxist view of history influenced Antonio Gramsci and helped give Italian Eurocommunism its distinctive flexibility. His concepts of 'genetic method', 'social morphology', 'philosophy of praxis' and 'social pedagogy' are indications of this attempt.

GEOFFREY HUNT

LACAN, JACQUES (1901–81)

Jacques Lacan was a French psychoanalyst and philosopher whose contribution to philosophy derives from his consistent and thoroughgoing reinterpretation of Freud's writings in the light of Heidegger and Hegel as well as structuralist linguistics and anthropology. Whereas Freud himself had disparaged philosophical speculation, claiming for himself the mantle of the natural scientist, Lacan demonstrates psychoanalysis to be a rigorous philosophical position. Specifically, Lacan suggests that the Freudian unconscious is best understood as the effect of language (what he calls 'the symbolic') upon human behaviour.

THOMAS BROCKELMAN

LAKATOS, IMRE (1922–74)

Imre Lakatos made important contributions to the philosophy of mathematics and of science. His 'Proofs and Refutations' (1963–4) develops a novel account of mathematical discovery. It shows that counterexamples ('refutations') play an important role in mathematics as well as in science and argues that both proofs and theorems are gradually improved by searching for counterexamples and by systematic 'proof analysis'. His 'methodology of scientific research programmes' (which he presented as a 'synthesis' of the accounts of science given by

Popper and by Kuhn) is based on the idea that science is best analysed, not in terms of single theories, but in terms of broader units called research programmes. Such programmes issue in particular theories, but in a way again governed by clear-cut heuristic principles. Lakatos claimed that his account supplies the sharp criteria of 'progress' and 'degeneration' missing from Kuhn's account, and hence captures the 'rationality' of scientific development. Lakatos also articulated a 'meta-methodology' for appraising rival methodologies of science in terms of the 'rational reconstructions' of history they provide.

JOHN WORRALL

LANGE, FRIEDRICH ALBERT (1828–75)

A German philosopher, social scientist and political activist, Lange was best known for his study of the history of materialism. He was a leading proponent of Neo-Kantianism, a critic of speculative metaphysics, and a defender of the view that philosophy should incorporate the findings of the exact sciences. As a social scientist, Lange described the emergence of a social Darwinian 'struggle for existence' in modern times due to the rapid advancement of industrialization and a growing conflict of interest among social classes.

Cognizant of the scientific trends of his time, Lange anticipated some of the central ideas of pragmatism and adopted a form of conventionalism in regard to scientific principles and concepts. Although sympathetic to materialism, Lange also saw the inevitability of an idealist element in interpretations of natural phenomena and insisted on the importance of projecting ethical, social and aesthetic ideals.

GEORGE J. STACK

LANGER, SUSANNE KATHERINA KNAUTH (1895–1985)

With roots in logic, philosophy of language and philosophy of mind, Susanne Langer sought to explicate the meaning and cognitive import of art works by developing a theory of symbolism that located works of art at the centre of a network of relations based firmly on semantic theory. Art works were non-discursive, presentational symbols that expressed an artist's 'life of feeling', by which observers, through a process of immediate apprehension (or intuition) came to acquire knowledge.

LANGUAGE, INNATENESS OF

Is there any innate knowledge? What is it to speak and understand a language? These are old questions, but it was the twentieth-century linguist, Noam Chomsky, who forged a connection between them, arguing that mastery of a language is, in part, a matter of knowing its grammar, and that much of our knowledge of grammar is inborn.

Rejecting the empiricism that had dominated Anglo-American philosophy, psychology and linguistics for the first half of this century, Chomsky argued that the task of learning a language is so difficult, and the linguistic evidence available to the learner so meagre, that language acquisition would be impossible unless some of the knowledge eventually attained were innate. He proposed that learners bring to their task knowledge of a 'Universal Grammar', describing structural features common to all natural languages, and that it is this knowledge that enables us to master our native tongues.

Chomsky's position is *nativist* because it proposes that the inborn knowledge facilitating learning is *domain-specific*. On an empiricist view, our innate ability to learn from experience (for example, to form associations among ideas) applies equally in any task domain. On the nativist view, by contrast, we are equipped with special-purpose learning strategies, each suited to its own peculiar subject-matter.

Chomsky's nativism spurred a flurry of interest as theorists leaped to explore its conceptual and empirical implications. As a consequence of his work, language acquisition is today a major focus of cognitive science research.

FIONA COWIE

LANGUAGE OF THOUGHT

The 'language of thought' is a formal language that is postulated to be encoded in the brains of intelligent creatures as a vehicle for their thought. It is an open question whether it resembles any 'natural' language *spoken* by anyone. Indeed, it could well be encoded in the brains of people who claim not to 'think in words', or even by intelligent creatures (for example, chimpanzees) incapable of *speaking* any language at all. Its chief function is to be a medium of *representation* over which the

computations posited by cognitive psychologists are defined. Its language-like structure is thought to afford the best explanation of such facts about animals as the productivity, systematicity and (hyper-)intensionality of their thought, the promiscuity of their attitudes, and their ability to reason in familiar deductive, inductive and practical ways.

GEORGES REY

LANGUAGE, PHILOSOPHY OF

Introduction

Philosophical interest in language, while ancient and enduring, has blossomed anew in the past century. There are three key historical sources of current interest, and three intellectual concerns which sustain it.

Philosophers nowadays often aspire to systematic and even mathematically rigorous accounts of language; these philosophers are in one way or another heirs to Gottlob Frege, Bertrand Russell, Ludwig Wittgenstein and the logical positivists, who strove to employ rigorous accounts of logic and of meaning in attempts to penetrate, and in some cases to dispel, traditional philosophical questions (see Logical positivism). Contemporary philosophers, too, are often attentive to the roles that philosophically interesting words (like 'know', 'true', 'good' and 'free') play in ordinary linguistic usage; these philosophers inherit from 'ordinary language philosophers', including G.E. Moore, J.L. Austin and again Wittgenstein, the strategy of finding clues to deep philosophical questions through scrutiny of the workaday usage of the words in which the philosophical questions are framed.

Philosophical interest in language is maintained by foundational and conceptual questions in linguistics, quintessentially philosophical problems about the connections between mind, language and the world, and issues about philosophical methodology. These springs sustain a rich and fascinating field of philosophy concerned with representation, communication, meaning and truth.

1 Philosophy of linguistics

Language is an impressive and fascinating human capacity, and human languages are strikingly powerful and complex systems. The science of this capacity and of these systems is linguistics. Like other sciences, and perhaps to an unusual degree, linguistics confronts difficult foundational, methodological and conceptual issues.

When studying a human language, linguists seek systematic explanations of its *syntax* (the organization of the language's properly constructed expressions, such as phrases and sentences; see Syntax), its *semantics* (the ways expressions exhibit and contribute to meaning; see Semantics), and its *pragmatics* (the practices of communication in which the expressions find use; see Pragmatics).

The study of syntax has been guided since the 1960s by the work of Noam Chomsky, who, in reaction to earlier behaviourist and structuralist movements in linguistics (see Behaviourism, analytic; Behaviourism, methodological and scientific; Structuralism in linguistics; Saussure, F. de), takes an unapologetically cognitivist approach. Human linguistic capacities, he holds, issue from a dedicated cognitive faculty whose structure is the proper topic of linguistics. Indeed, Chomsky construes at least the study of syntax and (large parts of) semantics as attempts to uncover cognitive structures. Finding impressive commonalties among all known natural languages, and noting the paucity of evidence and instruction available to children learning a language, Chomsky suggests that surprisingly many features of natural languages stem from innate characteristics of the language faculty (see Chomsky, N.; Language, innateness of).

Whereas contemporary philosophers have tended to stay at a remove from work in syntax, discussing rather than doing it, semantics is another matter entirely. Here many of the great strides have been made by philosophers, including Gottlob Frege, Bertrand Russell, Ludwig Wittgenstein, Rudolf Carnap, Richard Montague and Saul Kripke. (However, quite a number of linguists and logicians who do not call themselves philosophers also have contributed heavily to semantics.) One major strand in semantics in the past century has consisted in the development and careful application of formal, mathematical models for characterizing linguistic form and meaning (see Semantics, game-theoretic; Semantics, possible worlds; Semantics, situation).

Pragmatics, at least as much as semantics, has benefited from the contributions of philosophers. Philosophical interest in pragmatics typically has had its source in a prior interest in semantics – in a desire to understand how meaning and truth are situated in the concrete practices of linguistic communication. The later Wittgenstein, for instance, reminds us of the vast variety of uses in

which linguistic expressions participate, and warns of the danger of assuming that there is something aptly called their *meanings* which we might uncover through philosophy. J.L. AUSTIN seeks in subtleties of usage clues to the meanings of philosophically interesting terms like 'intentional' and 'true'. Austin keeps a careful eye to the several different things one does all at once when one performs a 'speech act' (for instance: uttering a sound, voicing the sentence 'J'ai faim', saying that one is hungry, hinting that one's companion might share their meal, and causing them to do so). His taxonomy has provided the basis of much subsequent work (see SPEECH ACTS; PERFORMATIVES). H.P. GRICE, while critical of some of Austin's methods, shared the aim of distilling meaning from the murky waters of use. Grice portrays conversation as a rational, cooperative enterprise, and in his account a number of conceptions of meaning figure as central strategies and tools for achieving communicative purposes. Grice's main concern was philosophical methodology (see §3), but his proposals have proven extremely popular among linguists interested in pragmatics (see COMMUNICATION AND INTENTION). Recently, philosophers and linguists have become increasingly persuaded that pragmatic concerns, far from being mere addenda to semantics, are crucial to the questions of where meaning comes from, in what it consists, and how the many incompletenesses and flexibilities in linguistic meaning are overcome and exploited in fixing what speakers mean by their words on particular occasions (see PRAGMATICS; IMPLICATURE; METAPHOR).

Our focus on language should not omit a field of study with a rather broader scope, namely *semiotics*, which is the study of signs and signification in general, whether linguistic or not. In the view of the scholars in this field, the study of linguistic meaning should be situated in a more general project which encompasses gestural communication, artistic expression, animal signalling, and other varieties of information transfer (see SEMIOTICS; ANIMAL LANGUAGE AND THOUGHT).

2 Meaning: language, mind and world

Philosophy aims at intellectually responsible accounts of the most basic and general aspects of reality. Part of what it is to provide an intellectually responsible account, clearly, is for us to make sense of our own place in reality – as, among other things, beings who conceive and formulate descriptions and explanations of it.

In framing issues about our roles as describers and explainers, philosophers commonly draw a triangle in which lines connect 'Language', 'Mind' and 'World'. The three lines represent relations that are keys to understanding our place in reality. These relations in one or another way constitute the *meaningfulness* of language.

Mind ↔ World. Between Mind and World there are a number of crucial relations studied by philosophers of mind. Among these are perception, action, the mind's bodily constitution and intentionality (the mind's ability to think *about* what is in the world) (see MIND, PHILOSOPHY OF).

Mind → Language. Using and understanding language is a heavily mental activity. Further, this activity seems to be what the real existence of meaningful language consists in. In short, mind invests *meaning* in language.

Theorists of language focus on the Mind/Language connection when they consider *understanding* to be the cornerstone concept, holding, for instance, that an account of meaning for a given language is simply an account of what constitutes the ability to understand it. Philosophy has seen a variety of accounts of wherein understanding consists. Many have been attracted to the view that understanding is a matter of associating the correct ideas or concepts with words (see, for instance, LOCKE, J.; FREGE, G.; LANGUAGE OF THOUGHT). Others have equated understanding with knowing the requirements for accurate or apt use of words and sentences (see, for instance, DAVIDSON, D.; DUMMETT, M.A.E.). Still others find the key to understanding in one's ability to discern the communicative goals of speakers and writers (see, for instance, GRICE, H.P.), or more directly in one's ability to 'pass' linguistically, without censure (see, for instance, WITTGENSTEIN, L.J.J.). Certainly, these approaches do not exclude one another.

Some philosophers focus more on production than consumption – on the speaker's side of things – analysing linguistic meaning in terms of the goals and practices of speakers, and in terms of relations among communities of speakers (see GRICE, H.P.; COMMUNICATION AND INTENTION).

Many of the philosophers who see understanding and use as the keys to linguistic meaning have held that the meaningfulness of language in some sense derives from mental content, perhaps including the contents of beliefs, thoughts and concepts. This enhances the interest of *cognitive semantics*, which is a thriving field of study (see SEMANTICS; SEMANTICS, CONCEPTUAL ROLE).

It has not gone unquestioned that mind indeed can assign meaning to language, and in fact scepticism about this has figured quite prominently in philosophical discussions of language. Wittgenstein has been read as at least flirting with scepticism that there is anything our minds *can* do that would constitute meaning one thing rather than another

(see Wittgenstein, L.J.J. §§10–12; Meaning and rule-following; Private states and language). W.V. Quine, starting from the thought that meaning is whatever good translation captures, and on arguments that good translation is not squarely dictated by any real facts, concludes that meaning is highly indeterminate. Quine is not alone in the view that linguistic and mental meaning are best seen not as 'out there' to be discovered, but rather as partly constituted or constructed by our practices of interpreting and translating (see Quine, W.V.; Davidson, D.; Dennett, D.C.; Lewis, D.K.; Radical translation and radical interpretation).

Language → Mind. If mind assigns meaning to language, so also language *enables* and *channels* mind. Acquiring and trafficking in a language brings one concepts, thoughts and habits of thought, with all sorts of consequences (see Sapir-Whorf Hypothesis). Indeed, having language is so crucial to our ability to frame the sophisticated thoughts that appear essential to language-use and understanding that many doubt whether mind is 'prior' to language in any interesting sense (see Davidson, D.).

Language ↔ World. Since language is the vehicle of our descriptions and explanations of reality, philosophers are concerned about what if anything makes for a *true* or *apt* characterization of reality. Philosophers have these concerns for reasons of philosophical methodology (which we will come to in a moment), but also owing to the naturalness and plausibility of a certain picture of meaning.

According to this picture, the key to meaning is the notion of a *truth-condition*. A statement's meaning determines a condition that must be met if it is to be true. For example, my statement 'Ireland is larger than Manhattan', given what it means, is true just in case a certain state of affairs obtains (namely, a certain island's being larger than a certain other island). According to the truth-conditional picture of meaning, the core of what a statement *means* is its truth-condition – which helps determine the way reality is *said to be* in it – and the core of what a word means is the contribution it makes to this (perhaps, in the case of certain sorts of word, this would be what the word *refers* to) (see Semantics; Meaning and truth; Reference).

While the truth-conditional picture of meaning has dominated semantics, a serious challenge has been presented by philosophers, including Michael Dummett, who urge that the key to meaning is a notion of *correct use*. According to this alternative picture, the core of a sentence's meaning is the rule for its appropriate utterance. Of course, the two pictures converge if sentences are correctly used exactly when they are true. The interest of the distinction emerges only when (a 'realist' conception of) truth is dislodged from this role, whether because of scepticism about truth itself, or because truth is seen as too remote from the crucible of social practice to be the meaning-relevant criterion for correct use (see Realism and antirealism; Intuitionistic logic and antirealism; Meaning and verification; Dummett, M.A.E.; Truth, pragmatic theory of; Truth, deflationary theories of; Truth, coherence theory of; Truth, correspondence theory of). The challenge illustrates a sense in which the Mind/Language and Language/World connections can seem to place a tension on the notion of meaning (meaning is whatever we cognitively *grasp*, while the meaning of language is its bearing on the world).

3 Linguistic philosophy

Apart from language's interest as a target of science and its centrality to our self-conception as describers of reality, language plays a key methodological role in philosophy. It is this role perhaps more than anything else that has explained the continued close attention paid to language in the past century by philosophers working in such varied areas as epistemology, aesthetics, ethics, metaphysics, the philosophy of science and the philosophy of mind.

The methodological role of language in philosophy is most easily explained by example. A philosopher is interested in the nature of value; they want to know *what goodness is*. Language enters when they observe that goodness is what is attributed when we *say* of a thing that it 'is good'. So the philosopher focuses on certain statements, and seeks an understanding of what such statements *mean* and in general of how they work. They explore whether such statements are ever objectively true or false, whether their truth or aptness varies from speaker to speaker, whether a satisfying explanation of them entails that the word 'good' refers to or expresses a genuine characteristic (of actions, states of affairs, persons, and so on), and how their meaning relates to the distinctive sorts of *endorsement* that such statements commonly convey (see Emotive meaning).

The pattern exhibited in the example of value is apparent throughout philosophy. We are interested in knowledge, fiction, necessity, causation, or sensation, so we find ourselves studying statements *about* what interests us: statements attributing knowledge, describing fictions, asserting necessities, assigning causes and reporting sensations. Tools from the philosophy of language make available quite a number of views about what these statements mean and in general about how they do their expressive and communicative work; and these views inform and support philosophical

positions on the real objects of philosophical interest. There have been dramatic and no doubt exaggerated claims about such techniques – for instance, that philosophy should simply *consist* in this sort of study of language. But it is if anything an understatement to say that linguistic sophistication has deepened philosophical understanding and has advanced debate in nearly all areas of philosophy.

MARK CRIMMINS

LATIN AMERICA, PHILOSOPHY IN

Geographically, Latin America extends from the Mexican–US border to those regions of Antarctica to which various Latin American countries have laid claim. It includes the Spanish-speaking Caribbean. Philosophy in Latin America dates from pre-Columbian (before 1492 in Hispanic America) and precabralian times (before 1500 in Brazil).

1 Latin American philosophy up to the nineteenth century

Indigenous cultures, particularly the Aztecs, Mayas, Incas and Tupi-Guarani, produced interesting and sophisticated thought systems centuries before the arrival of Europeans in America. Many cultural artefacts were lost or destroyed so that study of this period involves many challenges in deciphering the subtleties and complexities of the earliest thought in Latin America. Indigenous cosmologies were often linked to phenomena in the natural world.

Academic philosophy started up in the sixteenth century when the Catholic church began to establish schools, monasteries, convents and seminaries in Latin America. If the encounter with the New World had significant impact on the European mind, this was not initially reflected in the philosophy being taught and written in the sixteenth and seventeenth centuries, which tended to restate and reinforce medieval values. However, intriguing writings on ethics and jurisprudence grew out of the contact between Spain and Latin America. Essentially, these writings analysed the relationship between cultural differences and human rights. The Dominican friar Bartolomé de las Casas was a pivotal figure who defended the rights of native and African peoples living in the Indies in the sixteenth century.

With a few notable exceptions, the seventeenth century was largely moribund philosophically because most efforts were directed towards using academic thought to maintain the status quo, which reinforced a fundamentally medieval worldview. The main philosophical task involved justifying and protecting the Catholic faith against Protestantism and science. Scholasticism was the dominant trend. However, there were some exceptions to the dominant practices in the form of several remarkable historical and philosophical figures. Antonio Rubio's studies on logic are remarkably advanced. Juana Inés de la Cruz had a brilliant philosophical mind and is usually considered one of the earliest feminist thinkers in America.

Intellectually, the eighteenth century continued this calm traditionalism until mid-century when a generation of Jesuits tried to break with the thought of Aristotle and bring philosophy into 'modernity'. They were primarily influenced by post-Renaissance Italian and French philosophy. However, the Jesuit order was expelled from the Spanish-speaking world in 1767. This delayed the introduction of proto-modern European philosophy in Latin America. The eighteenth century has become the subject of much revisionist philosophical study, particularly in Mexico.

Academic philosophy still did not broaden in the early nineteenth century because of political turmoil both in various Latin American countries and in Europe. Universities occasionally were closed, inhibiting academic philosophical progress as universities were the locus of much philosophical

activity. A more productive forum for philosophy was often the political arena in which thoughtful essays of ideas were written by non-academics on themes such as constitutional government, progress and autonomy.

Later in the nineteenth century and into the early twentieth, positivism eventually became entrenched in most Latin American countries. This movement claimed to be an objective methodology of the sciences. It was widely believed that scientific doctrines could provide the most efficient management of society through educational and political reforms. Auguste COMTE and Herbert SPENCER were the primary positivist influences in Latin America.

2 Latin American philosophy in the twentieth century

In the early twentieth century new intellectual movements began. Arising from these was a strong, thorough-going anti-positivist backlash. Ideas that positivists had promoted as 'scientific' were rejected by anti-positivists for being scientistic. Philosophers entertained idealism, vitalism, pragmatism and various political and social philosophies. Neo-Thomist thought continued to be widely studied, primarily in the Catholic universities.

A focus on regional thought in Latin America was an outgrowth of anti-positivist thought and a consequence of the arrival of Spanish philosophers who were exiled after the fall of Republican Spain. The writings of the Spaniard, José ORTEGA Y GASSET, were widely influential in shaping Latin American philosophical reflections. Philosophers addressed the question of authenticity as they explored whether Latin Americans were simply adopting European philosophies, or whether they themselves had any authentic philosophy to offer. Many concluded that Latin Americans were adapting, rather than adopting European philosophies to their own reality.

This process of critical self-examination, or 'autognosis', was twofold. First, philosophers in individual countries and regions of Latin America sought to identify what was unique or distinctive about their thought or being. Later, philosophical contributions made by Latin America as a whole were compared and contrasted with those of other regions in the world. Studying Latin American thought in comparative perspective engendered a debate of considerable longevity over whether 'Latin American philosophy' exists or whether 'philosophy in Latin America' is a more accurate denotation. Every Latin American country, including Puerto Rico, can be argued to possess unique philosophical traditions. At the same time there exists an extensive body of argument and commentary on what kind of philosophy, if any, can claim to be 'universal'.

Since analytical philosophy presents perspectives, methods and projects which claim to have universal appeal and applicability, it is often embraced in academic circles and is most frequently entrenched institutionally in Mexico, Brazil and Argentina. Analytical philosophy in these countries, while not obviously a response to immediate regional social, political or economic circumstances, serves to include and validate its adherents in international circles by adopting a style widely practised and accepted by mainstream Anglo-American academic philosophy. Attracted to the linguistic 'rigour' of analytical philosophy, some adherents claim that it is the only way to do 'real philosophy'.

The late twentieth century reveals that it is possible to speak of both 'Latin American philosophy' and 'philosophy in Latin America'. Some areas of philosophical research imbued with regional and cosmopolitan appeal are cultural identity, feminist thought, liberation philosophy, marginality and Marxist thought in Latin America. Many of these areas are profoundly engaged with Latin American realities in historical context. Rather than blindly adopting canonical Western philosophical paradigms, writers in these traditions seek to broaden the definition of what is human by convincingly articulating and incorporating Latin American experience and values into both the crucial discourses of philosophy and the pressing themes of the modern world (see MARGINALITY).

Marxist philosophy has been and most likely will continue to be significant in Latin America, partly because of continuing problems of economic disparities. Concerns with retributive justice, human rights and issues of power and truth, as well as the belief that Marxist theory more accurately describes reality, contribute to the vitality of this thought. Despite the collapse of the Soviet Union and the passing of Maoism in China, for many the Cuban Revolution of 1959 is still idealized because it continues to threaten the US 'monster' to the north, while advancing the notion of a supportive, egalitarian and responsible community. The Peruvian José Carlos Mariátegui was an original Latin American Marxist thinker whose thought has generated interest and respect internationally.

One of the best-known and most interesting contributions of modern Latin American intellectual life is liberation philosophy. The philosophical movement originated in Argentina, although many of its practitioners reside in other Latin American countries. Philosophy of liberation should not be confused with liberation theology. Philosophy of

liberation attempts to explain philosophically the theoretical underpinnings of social and political phenomena, such as dependency, and reinforces theology of liberation. These movements are responses to significant events in twentieth-century Latin America such as the Cuban Revolution (1959), the Argentine 'Dirty war' (1976–1983) and repressive regimes which began in Guatemala in 1954, in Brazil in 1964 and in Chile in 1973. Other political topics for these writers included populism, Marxism and Peronism. Philosophy of liberation differs from theology of liberation, Latin Americanist philosophy and Marxist philosophy especially in terms of its more limited accessibility. Philosophers of liberation employ a complex and specialized vocabulary which requires initiation on the part of readers. In addition, philosophy of liberation is not a unified movement: it is more appropriate to speak of philosophies of liberation. Such fragmentation in this field can be partly explained by the political orientations of thinkers whose views range from the extreme left to the extreme right. Their philosophical influences vary widely and include Francophone, German and other Latin American thinkers.

Philosophical activity in Latin America is characterized by a tremendous diversity of focus and methodologies. Latin Americans are keenly aware of philosophical developments in the rest of the world and thus entertain a variety of philosophical stances: progressive and conservative, pragmatist and idealist, materialist and spiritualist. Numerous philosophical interests and projects exist in Latin America because of a diversified and active philosophical profession, an interested public, some government support, a cultural awareness of other continents among the educated and non-educated alike and a widespread faith in education as a key to development.

AMY A. OLIVER

LAW AND MORALITY

Introduction

Within the tradition of natural law thinking which finds its roots in the philosophies of Aristotle and Aquinas, the political community has generally been understood in terms of a fundamental goal: that of fostering the ethical good of citizens. Law, on this conception, should seek to inculcate habits of good conduct, and should support a social environment which will encourage citizens to pursue worthy goals, and to lead valuable lives. Pragmatic considerations may sometimes suggest the wisdom of restraint in the pursuit of these goals, and citizens may therefore, on appropriate occasions, be left free to indulge depraved tastes or otherwise fall short of acceptable standards. Such pragmatic arguments for the freedom to engage in vice, however, do not call into question the legitimacy of the state's concern with individual morality.

By contrast the liberal tradition has tended to place constraints of principle upon the scope and aims of the law. The most influential such attempt was J.S. Mill's advocacy of 'the harm principle': that the law may forbid only such behaviour as is liable to cause harm to persons other than the agent. Many difficulties surround this and other, more recent, attempts to formulate and defend constraining principles. For instance, should one take into account only the immediate effects of behaviour, or more remote and diffuse effects as well? Thus it is argued that immoral behaviour which in the short term 'harms nobody' may, in the long run, lead to a decline in morality in society at large and to diffuse harmful effects.

1 Two traditions

The attempt to delimit principles which confine and constrain the proper scope of legal and governmental interference is inseparable from the liberal tradition: one need only think of Locke's attempt to define such a sphere of legitimacy by reference to a body of natural rights. Yet the attempt to delineate such principles has not always focused in a clear and circumscribed way upon the particular problem of an allegedly private sphere of morality. Thus when Locke, in his *Letter Concerning Toleration* (1689), seeks to defend religious toleration, he seems to do so not by reliance on his theory of natural rights and social contract, but by means of a pragmatic argument which would have sat comfortably within the assumptions of the Thomist natural law tradition: intolerance is, for Locke, pointlessly ineffectual rather than a violation of a distinct constraining political principle (see LOCKE, J. §1). Debate began to focus clearly on the idea of constraining principles precluding the state from interference with private immorality only in consequence of essays such as Wilhelm von Humboldt's *The Sphere and Duties of Government* (published posthumously in 1852) and J.S. Mill's *On Liberty*

(1859) (see §2 below). The latter work has exerted the most fundamental influence in English-speaking countries.

Before we examine Mill's claims, however, it is worth making a couple of preliminary points. In particular, we should reflect upon the diverse motivations which may underpin rejection of the Aristotelian tradition of political thought, and may lead to the search for principles constraining the community's entitlement to enforce 'private' moral standards. It is often thought that the liberal is committed to a 'subjectivist' or noncognitivist understanding of moral judgment, and that the liberal concern for tolerance is simply a consequence of such subjectivism (see MORAL JUDGMENT §1). Such an interpretation must, however, be a mistake: for, if moral judgments are simply expressions of subjective emotion or attitude, this must apply to moral judgments about the importance of tolerance along with all other moral judgments. A better reading of liberalism would see it as flowing from the inability to reach *agreement* on moral questions, rather than from the supposedly 'subjective' character of moral judgments. This reading does not succumb to the self-subverting character of an appeal to subjectivism, but it does have its problems. In some versions, for example, it can seem to imply that the need for consensus among those who disagree is the rationale for restricting the state's role; but this seems to make the argument for tolerance dependent upon the existence of a balance of power between contending factions.

Finally, one popular line of defence claims that liberalism is reliant neither upon moral subjectivism nor upon the inconclusive nature of moral argument, but upon the value of autonomous choice: it is good that people choose their own projects and lifestyles, even when they choose degrading or unworthy options (see AUTONOMY, ETHICAL). The problem posed by this approach is that it is not wholly clear that the approach can be contrasted in any very fruitful way with the concerns of the Aristotelian tradition. After all, the Aristotelian might claim that *being freely chosen* is an essential condition of a good life, so that the state's concern to encourage good lives itself dictates a concern to protect autonomy. Viewed from this perspective, the debate with liberalism would seem to be a pragmatic argument within the parameters of the Aristotelian tradition.

Such a reconceptualization of the terrain might well be viewed as damaging by many liberals. For many of the critics of Mill and of more recent liberals have directed their fire at the very idea of abstract principles constraining legitimate interference with a realm of supposedly 'private' conduct. They have been less concerned to oppose the concrete applications of these principles advocated by the liberals themselves. A characteristic example is James Fitzjames Stephen, who, in his book *Liberty, Equality, Fraternity*, wrote as follows:

> I object rather to Mr. Mill's theory than to his practical conclusions.... The objection which I make to most of his statements on the subject is, that in order to justify in practice what might be justified on narrow and special grounds, he lays down a theory incorrect in itself and tending to confirm views which might become practically mischievous.

2 Mill's 'harm principle'

Mill proposes what he describes as a 'very simple principle' as being 'entitled to govern absolutely the dealings of society with the individual in the way of compulsion and control'. The principle asserted that 'The only purpose for which power can rightfully be exercised over any member of a civilised community, against his will, is to prevent harm to others' (*On Liberty* 1859).

Mill's 'harm principle' has sometimes been taken to suggest an atomistic view of society such that there is an area of private conduct which does not impinge on others at all, and which falls outside the law's proper domain for that reason. As his critics were quick to point out, only the most trivial actions are devoid of effects upon others. In spite of the encouragement that Mill gives to this interpretation in some of his language, however, he explicitly conceded that 'self-regarding' actions may nevertheless affect other people. His principle is not intended to demarcate an area of conduct that is beyond the law's remit, so much as a type of reason to which the community should restrict itself: in considering whether an action should be prohibited, only *some* of the effects of an action should be taken into account. In particular, the action's effects in 'harming' others may be taken account of, while the effects upon the actor himself must be disregarded, as must the disapproval of unaffected third parties who consider the act immoral (see PATERNALISM).

In other ways, however, the suggestion that Mill adopts an unduly 'atomistic' view might seem to have some validity. For, if the harm principle is construed as prescribing a focus on fairly immediate and individuated harms, it may lead us to neglect the importance of sustaining social institutions that may be undermined in more oblique ways by the law's failure to uphold conventional moral standards.

One reply to this line of attack might be that nothing in the harm principle compels such a narrowly individuated focus: if the erosion of some social institution *is* a probable consequence of liberalization in an area of conduct, and if that erosion would be harmful, the harm principle legitimates our taking such considerations into account. The reply is problematic, however, in so far as a harm principle which invites us to take account of quite remote and diffuse effects threatens to prove empty and insubstantial in application. Mill himself is quite ready to accept that highly diffuse effects upon others can constitute 'harm' (he is, for example, critical on this ground of the unrestricted right to procreate) but the concession does represent an erosion of the integrity of the principle.

A number of other serious problems are associated with the harm principle. One question concerns the compatibility of the principle with Mill's commitment to utilitarianism (see UTILITARIANISM). For should not a utilitarian legislator take account of *all* of the effects of an action, before deciding upon its prohibition? If some people suffer deep unhappiness at the very thought of acts of which they disapprove being performed in private, how can this unhappiness be justifiably *ignored* from the viewpoint of utility? It has been suggested that a utilitarian legislator should disregard such unhappiness in so far as it flows from the adoption of nonutilitarian moral views. But even if this argument could be sustained, it would not go far enough: I may be upset by the thought of acts which I consider simply disgusting rather than immoral; and, in any case, the exclusion of harm to the actor himself remains unexplained by this approach.

It is likely that Mill saw the harm principle as an intermediate maxim, by which utilitarians should regulate their conduct, with the ultimate objective of advancing overall happiness in the long run. Such a view avoids inconsistency, however, only at the price of rendering the entire case dependent on largely empirical claims about the long-term effects of individual liberty. Mill's defence of the harm principle could in this way be thought to manifest an undue and ungrounded optimism. Given the aggregative conception of the common good espoused by utilitarianism, it would be remarkably fortunate if the best way of advancing the collective welfare was invariably to protect individual freedoms.

Quite apart from the compatibility or otherwise of the harm principle with Mill's utilitarianism, however, is the question of the meaning of 'harm' itself. For it has been repeatedly and justifiably pointed out that the question of what constitutes harm is an evaluative question which cannot in the end be separated from our wider ethical beliefs. Attempts, such as that of Joel Feinberg, to analyse harm in terms of setbacks to interests simply reformulate the problem as one concerning the nature and content of our interests. Yet, without some morally neutral account of harm, Mill's principle seems to do little to exclude criminal prohibitions which are simply based upon moral disapproval of the actor's conduct. Consider, for example, the harm principle in its application to the debate about pornography. One issue concerns the suggestion that pornography fosters a social environment within which violent crimes against women are more likely: this argument appeals to an uncontroversial instance of harm, but makes the issue depend upon highly contestable empirical theses about the effects of pornography. What then if someone suggests that women are harmed *intrinsically* by pornography, in the sense that all women are harmed when some women are depicted as being objects available for sexual gratification? This suggestion employs a notion of harm which might not be universally accepted, but it challenges us to articulate criteria for what is to be regarded as harm (see PORNOGRAPHY).

A relevant suggestion has been made (in a slightly different context) by Brian Barry. He suggests (1995) that 'harm' might be defined in terms of what the great majority of people, having divergent conceptions of the good, would nevertheless agree upon as 'bad'. The suggestion builds upon the sound insight that people may have divergent ethical conceptions which nevertheless have an extensive area of overlap; but in requiring something short of complete universality and unanimity, Barry's approach seems in danger of making the scope of the harm principle itself depend upon majoritarian politics of a kind that Mill was concerned to constrain.

The above arguments may or may not be fatal to Mill's position. They do not render the harm principle wholly vacuous, because that principle serves, at a minimum, to direct our attention to an action's effects on others, rather than on the actor himself; but, if sound, the arguments dramatically reduce the value of the principle as a limitation upon the proper scope of the state's coercive power.

Even the requirement that we should have regard only to effects upon others may be a less substantial constraint than it seems, for we must remember Mill's acceptance of diffuse effects as 'harm'. Acts which are widely considered to be immoral may, in the first instance, affect only the actor himself; but, by creating a communal environment in which such acts are tolerated, they may make it harder (for example) to educate children into moral standards of conduct. When combined with the impossibility of offering a morally neutral account of the nature

of 'harm', such diffuse effects seem to reduce the significance of Mill's principle to vanishing point.

3 The Hart/Devlin debate

A concern for such diffuse effects of immoral conduct lies at the bottom of an argument presented by Lord Devlin in 1959, in a British Academy Maccabean Lecture in Jurisprudence. Lord Devlin was then a judge of the Queen's Bench Division of the High Court, becoming a Lord of Appeal in 1961. His Maccabean Lecture arose out of the Wolfenden Report on Homosexual Offences and Prostitution, which had been published in 1957, and which had articulated the principle that 'private immorality' should not be the concern of the criminal law. Devlin criticized this approach, on the ground that society depends for its survival upon the existence of a shared morality, and that it was therefore in principle possible for grossly immoral conduct to threaten the survival of the society. Consequently, society has a right to enforce its shared morality as a measure of self-protection. Devlin was concerned, not with the truth or falsehood of the relevant moral views, but solely with the fact that they were widely shared and fundamental to the society's stability.

H.L.A. Hart responded to Devlin's assault by pointing to the absence of empirical support for Devlin's claims that immorality could lead to social breakdown. But it has more recently been suggested (George 1993) that Devlin had in mind not a breakdown in social order so much as a loss of social cohesion, where people relate to each other purely on a basis of self-interest rather than on a basis of moral principle. If this interpretation is correct, it would make Devlin's claim both more plausible and less open to empirical refutation or confirmation.

Devlin acknowledged a debt to the Victorian judge and jurist James Fitzjames Stephen, whose book *Liberty, Equality, Fraternity* (1873) was a forceful attack upon Mill's theory. Stephen's approach was utilitarian in character, but he regarded Mill as having departed from the consistent utilitarianism of Bentham and James Mill. Hart described the works of Stephen and Devlin as revealing 'the outlook characteristic of the English judiciary'.

4 Dworkin on 'external preferences'

The 'goal-based' approach of utilitarianism is rejected by Ronald Dworkin in favour of what he calls a 'rights-based' approach; but, in reality, there are good grounds for considering his position to be a modified form of utilitarianism, rather than a radical rejection of that approach. Dworkin takes the view that, in so far as utilitarianism possesses any genuine moral appeal, that appeal is a consequence of the extent to which it expresses our belief in a 'right to equal concern and respect'. He argues, however, that the notion of equal concern and respect receives inadequate expression within utilitarianism to the extent that the utilitarian takes account not only of 'personal preferences' (preferences for what I myself do and receive) but also of 'external preferences' (my preferences about what others do or receive). A proper concern for equality would exclude the influence of external preferences by recognizing a 'right to moral independence': the right not to suffer disadvantage simply on the ground that others consider one's conceptions of a good life to be ignoble or wrong.

Dworkin believes that rights are best understood as 'trumps' over collective goals, and that, consequently, their philosophical justification is in part relative to the goals which have been adopted. The problem with taking account of external preferences (if a utilitarian goal has been adopted) is that the external preferences 'purport to occupy the same space' as the utilitarian theory itself: utilitarianism must be neutral between pushpin and poetry, but it cannot be neutral between itself and Nazism (for example).

Dworkin insists that this argument holds even when the external preferences are not based on any general moral or political theory: they still 'invade the space claimed by neutral utilitarianism'. It is difficult to see how this argument can be sustained, however. One cannot argue, for example, that a preference 'invades the space of utilitarianism' simply because, if fully satisfied, it would necessitate a distribution not recommended by utilitarianism. Such an approach would prescribe a decision procedure which was viciously circular: for one would have to decide upon the requirements of utility before one could say whether any particular preference should be taken into account in calculating those requirements.

In any case, could it not be said that Dworkin's approach fails to show equal concern for those whose wellbeing or utility is a function of their external preferences? Suppose that my sole concern is your welfare, and my life will be a failure if your happiness is not secure. How can equality of concern dictate that my wellbeing should be disregarded?

Many will consider that the proposed 'right to moral independence' is more attractive than is the justification which Dworkin proposes for it; but then, few if any theorists have argued that people should be disadvantaged simply in consequence of a widely held disapproval of their lifestyles, so perhaps the 'right' is not very substantial after all.

LAW, PHILOSOPHY OF

Introduction

Law has been a significant topic for philosophical discussion since its beginnings. Attempts to discover the principles of cosmic order, and to discover or secure the principles of order in human communities, have been the wellsprings of inquiry into law. Such inquiry has probed the nature and being of law, and its virtues, whether those that it is considered as intrinsically possessing, or those that ought to be cultivated by lawgivers, judges or engaged citizens. A dialectic of reason and will is to be found in philosophical speculation about the underpinning principles of law. On the one side, there is the idea that the cosmos itself, and human society too, contain immanent principles of rational or reasonable order, and this order must be capable of discovery or apprehension by rational (or 'reasonable') beings. On the other side, there is the view that order, especially in society and in human conduct, is not found but made, not disclosed to reason but asserted by acts of will. Either there is a 'law of reason – and nature' or there is a 'law by command of the sovereign – or of God'. A third possible element in the discussion may then enter, that of custom as the foundation of law.

Implicit in the opposition of reason and will is the question of practical reason: does reason have a truly practical role concerning ultimate ends and nonderivative principles of action, or is it only ancillary to the pursuit of ends or fulfilment of norms set by will? Alternatively, does reason already presuppose custom and usage, and enter the lists only by way of critique of current custom and usage? In either case, what is at issue is the very existence of such a thing as 'practical reason' (see Practical reason and ethics). For law is about human practice, about societal order enforced and upheld. If there can be a law of reason, it must be that reason is a practical as well as a speculative faculty. The radically opposed alternative sets will above reason, will oriented to the ends human beings happen to have. Norms and normative order depend then on what is willed in the way of patterns for conduct; reason plays only an ancillary part in the adjustment of means to ends.

A further fundamental set of questions concerns the linkage of the legal with the political. If law concerns good order, and if politics aims at good order in a polity, law must be a crucial part of politics; but in this case a subordinate part, for politics determines law, but not law politics. On the other hand, politics may be considered at least as much a matter of actual power-structures as a matter of speculation about their beneficial use for some postulated common good. In the latter case, we may see law as that which can in principle set limits on and control abuses of power. Politics is about power, law about the shaping and the limiting of power-structures. The issue then is how to make law a master of politics rather than its servant.

1 Law as reason

In the *Republic*, Plato depicts Thrasymachus, proponent of the thesis that justice is the will of the powerful, as being refuted comprehensively by Socrates (see Plato §14). The refutation postulates a human capability to discern principles of right societal conduct independently of any formal enactment or legislative decision made by somebody with power. These principles in their very nature are normative, not descriptive. In Aristotle, the same general idea emerges in the form of noticing that whereas much that is observed as law is locally variable and arbitrary, there appear to be fundamental common principles across different polities. Some principles may then be legal simply 'by enactment', but others seem to be so 'by nature'. Explorations of the nature of humans as rational and political animals may then help to underpin the idea of that which is right by nature, but that exploration is more the achievement of Aristotle's successors in the Stoic tradition than of himself (see Stoicism). Roman jurists adapted some of the Stoic ideas of natural law in their expositions of the civil law, and subsequently, for medieval and early modern Europe, the existence of the Justinianic compilation of the whole body of Roman law was held by many thinkers to embody in large measure the promise of law as 'written reason' (see Roman law).

In any event, the greatest flowering of the Aristotelian idea came with its fusion into the Christian tradition in the work of Thomas AQUINAS (§13), hugely influential as this has been in the developing of Catholic moral theology in the succeeding centuries. After at least a century of relative neglect among legal scholars, especially in the English-speaking world, the last quarter of the twentieth century has seen a strong revival of the Thomistic approach in the philosophy of law (see NATURAL LAW), with contemporary thinkers developing the idea of the basic goods implicit in human nature, and showing both how these can lead to the elaboration of moral principles, and then how positively enacted laws can be understood as concretizations of fundamental principles.

In the seventeenth century, other strands of essentially the same idea had led to the belief, for example, of Hugo GROTIUS, that basic principles of right conduct and hence of human rights are themselves ascertainable by intuition and reason (compare PUFENDORF, S.). Kant's representation of the principles of practical reason is the classical restatement of this position in its most philosophically rigorous form (see KANT, I. §§9–11; KANTIAN ETHICS §1).

In a wide sense, all these approaches may be ascribed to rationalism, as contrasted with voluntarism (see RATIONALISM; VOLUNTARISM). For they treat law, or its fundamental principles, as discoverable by rational and discursive means, independently of the intervention of any legislative will. They do not, of course, deny the need for legislative, or adjudicative or executive, will. Even if fundamental principles stand to reason, their detailed operationalization in actual societies requires processes of law-stating, law-applying and law-enforcement. But the issue is whether these are fundamentally answerable at the bar of reason and practical wisdom (*prudentia*), or not. To the extent that they are so answerable, we have a concept of some 'higher law', some law of reason, by which to justify, to measure and to criticize the actual practice of human legal institutions. If the rational derivation of this depends in some way on a teleological understanding of human nature and its relation to the creator and the rest of the created universe, we may reasonably enough call this a 'law of nature' or 'natural law'.

2 *Law as will*

But there is another possible account of higher law. It can be thought of as a law laid down by God for his creation. The divine will, not the divine reason, must be the source of law. It cannot be for created reason to presume to judge of the creator's wisdom. The omnipotence of the creator entails that the law will be whatever the creator wills it to be, and to be law by virtue of that will, not by any independent reason and nature of things. Indeed, the nature of things will be just what the creator wills it to be, and the names of things will be matters of convention derived from human linguistic usage. Concepts are not essences that guide us to essential meanings. Nominalism and voluntarism are inevitable bedfellows (see NOMINALISM).

It is therefore inaccurate to suppose that the theory of natural law as a kind of higher law presupposes rationalism. There can indeed be a voluntaristic species of 'natural law', though the voluntaristic tradition will more likely speak of 'divine law' or 'God's law' than of natural law *simpliciter* (see AUSTIN, J.). Moreover, one element in the religious upheavals associated with the Reformation was an insistence on the need for unmediated regard to the (scripturally revealed) divine law, rather than to the custom or tradition of sinful human institutions such as the Church. It is not for fallen human reason to set itself above or even beside the revealed will of God. But that revealed will must be received as a law binding above all others.

In this state of things it becomes questionable whether to accept any human law at all; and, on the voluntarist hypothesis, to see how law other than God's law can have any obligatory force at all. To the saving of human law there are only two possible moves: either it must be shown that God in fact wills our obedience to the very kings and other superiors we actually have (as in the theory of 'the divine right of kings'), or it must be the case that the binding will arises from the consent of human beings themselves, expressed through some original social contract. The divine will then enters the picture only to the extent of making obligatory the fulfilment of compacts voluntarily agreed, a point to which may be added a grimly Hobbesian acknowledgement that covenants without swords are but words, so the true binding force of the obligation of the law will derive from the effective might of the very ruler whom the social compact institutes in that office (see HOBBES, T. §§6–7). In this Hobbesian form, natural law has practically reached a vanishing point (though Locke's response envisages the state of nature as governed by reason in the form of a law of nature, grounding presocietal rights of human beings to life, liberty and estate (see LOCKE, J. §§9–10). The greatest legal expression of the Lockean vision of law, applied to expounding the English common law, is in the work of Sir William BLACKSTONE. The *coup de grâce* was administered by Hume and Bentham, the latter having as his particular target Blackstone's work. They argue that the social contract is a fifth wheel

on the carriage in either Hobbesian or Lockean form, since all the reasons that there are for obeying the law that we have supposedly agreed to apply with equal force even if we did not agree to it, and there is no evidence anywhere of any such agreement as a historical phenomenon (see BENTHAM, J.).

3 Law as custom

Whence then comes the law? Hume ascribes it to convention and custom primarily, coupled with reflection upon the pleasing quality (the utility) of rigorous observance of customary norms (see HUME, D. §3). Bentham and Austin restrict the role of custom or 'habit' to the issue of obedience. Whoever is habitually obeyed by the many in a numerous society is in a position to enforce their commands by effectively coercive sanctions up to and including death. Thus do they differentiate the positive law from other forms of so-called law such as scientific law, laws of honour, or personal moral codes. Law is such by command of a sovereign, the one habitually obeyed who habitually obeys no other (see SOVEREIGNTY).

Legal positivism of this stamp is an easy bedfellow with political utilitarianism, and programmes of legal reform. Codification of law is an associated ambition, justified on utilitarian grounds (see UTILITARIANISM; BECCARIA, C.B.; BENTHAM, J.). Codification is also a distinctive phenomenon of the early nineteenth century, product of the Enlightenment critique of the old customs of the *ancien régime*, though also of spadework in the exposition of civil law partly achieved under the aegis of late legal rationalism. After the Code Napoléon, promulgated in France in 1804, there followed a century of codification and legislative modernization of law in many places, and with this characteristically went approaches in legal philosophy that stress the essential emergence of law from a sovereign's will, or the will of the state as a rational association (in Hegelian vein; see HEGELIANISM). Nevertheless, this movement produced its own counter-movements, stressing the importance of the spirit of the people as the basis of law, or more prosaically locating it primarily in custom, a view particularly popular in the context of the common law.

Twentieth-century critics of classical positivism accuse its authors of confusing 'commands' with 'binding commands' (see KELSEN, H.) or of mislocating the roots of legislative authority in mere 'habit', rather than in the 'internal point of view' of those for whom the system within which authority is exercised has normative force (see HART, H.L.A.). The Kelsenian version of positivism rests it on the necessary presuppositions for a value-free science of law, and other thinkers have pursued further the question of 'legal science' (see BOBBIO, N.); the Hartian version rests it on the customs of at least the official and political classes in a state, whose practices concerning the recognition of certain criteria for the validity of legal rules define the ultimate 'living constitution' of a state, its 'rule of recognition' (see LEGAL POSITIVISM). Rival varieties of Hartian positivism have become salient in recent decades.

A notable offshoot of or development from positivistic legal study has been the development of ever-more rigorous approaches to conceptual analysis and categorization, seeking to account for the use of concepts like 'duty', 'right', 'ownership' and others in the framework of general legal norms. Hohfeld's analysis of 'fundamental legal conceptions' (see HOHFELD, W.N.) has had many followers and critics, and contemporaries in other traditions have taken a somewhat more psychologistic approach to the task. Reflection on legal concepts as institutions or 'institutional facts' has led to developing an 'institutional' theory of law that transforms what was originally a naturalistic conception into a positivistic one.

4 Laws and values

One way or another, whether in voluntaristic versions or in those that place more weight on customary or institutional aspects of law, nearly all forms of or approaches to legal positivism have insisted on the strong value-relevance of positive law. The matter of doubt has not been 'ought laws to be just?', but whether their being just is a condition of their being genuinely legal. The 'scientific' character of pure legal analysis has indeed been contrasted with the exercise of moral judgment or moral sentiment, or the engaging in ideological argumentation, that is involved in the critique of law as unjust or otherwise unsatisfactory from the viewpoint of human needs and aspirations. Some, however, have thought that critique itself can have a scientific or at least an objective basis, grounded in the fundamentals of human nature. Classical utilitarianism and nineteenth-century law reform have already been noted; they had successors in the 'jurisprudence of interests', and, albeit with certain qualifications, in the later twentieth-century 'economic analysis of law'.

The need to subject law to critique is obvious from many points of view, none more urgently than that which takes note of the burdensome impact of legal sanctions on human happiness and liberty. If laws characteristically carry punishments or awards of damages for their infraction, some theory to justify penal and compensatory institutions is called

for (see Crime and punishment; Justice, corrective). Whether there are any abstractly stateable limits to the legitimacy of interference with liberty through legal intervention has been another heated debate (see Law and morality).

Nevertheless, the positivists' claim that they can combine an a-moralistic conceptual analysis of law and its institutions with a readiness for critique of actual laws on moral and political grounds, and with a last-resort readiness to disobey or defy the law when it is unjust to an extreme, has been doubted by some. Gustav Radbruch felt himself driven by his experience of the Nazi years (and also, perhaps, by the implications of the radical voluntarism of Carl Schmitt) to abandon such a claim and to insist on a conceptually necessary minimum of basic justice in anything we can recognize as 'law' at all. The interpenetration of equity with law, and the interweaving of ideas of justice, equity and law, can be taken to point to a similar moral, and idealistic approaches to legal theory give a deeper grounding for such an approach.

5 *Law as politics*

However one takes one's stand on will against reason, or on natural law against legal positivism, most of the theoretical approaches so far considered give some way of accounting for the independent existence of law as a distinct social phenomenon. Law's independence, at least when underpinned by an independent judiciary, has been held to promise the possibility of effective control over arbitrary state action while at the same time guaranteeing at least the justice of formal equality to citizens and the degree of predictability allegedly desired by modern rational subjects. Here we have the 'rule of law' ideal that demands government under the forms of law and law in the form of clearly identifiable rules (see Rule of law (Rechtsstaat)). Yet the mere existence of some body of sacred or secular texts embodying rules of law is not enough for any socially realistic account of law, or for any politically persuasive vision of the rule of law (see Social theory and law). The statute book is not self-applying or self-interpreting. To secure the rule of law it is necessary to have prospective rules published to all. But, as L.L. Fuller points out, it is necessary that they be interpreted in a reasonable and purposive way, and faithfully carried into action by the officials of the state whose rules they are. How is this to be secured?

Many schools of thought, chief among them the realists (see Legal realism) in Europe and in the USA, have stressed the widely discretionary character of legal interpretation, both in relation to the general rules of the law, and in relation to the categorization of fact-situations as subsumable under the law for one purpose or another. On inspection, 'facts' can turn out to be as elusive as 'laws', and the study of legal processes of proof assumes a certain urgency. All in all, it is a serious and difficult question to discern what, if anything, can render decisions reasonably 'reckonable' given the broad discretion vested in those who interpret the law.

One form of response has been to find that law is reckonable not on the basis of the official rules and standard doctrine, but rather on the basis of the 'situation sense' of a judiciary with a common understanding of political and policy objectives underlying law. These insights of the 'realists' have been carried forward more boldly by contemporary feminist jurisprudence, one version of which finds social prejudice directing law through the biases of judges. Another version locates an inner masculinity in the legal rules themselves, even and especially at their most abstract; the asserted values of objectivity and impersonality ultimately come under question as presumptions of doubtful desirability.

Within more mainstream jurisprudence the developed response to realism has been to work out extended theories of the rule of law, acknowledging that law is more than positive rules but arguing for the existence of other mechanisms within law controlling the role of substantive elements in decision-making (see Causation in the law). Such responses find a certain coherence within law, but by contrast the more developed critical (including critical feminist) approaches argue that there are central fractures and fault lines within the law, reflecting ultimately competing political visions of human association, often summed up as individualism versus community-values. Ronald Dworkin's argument for coherence and integrity in law evokes the idea of an interpretive community, but seems too readily to assume that for any actual legal order there can be found a single consensual interpretive project, even in principle (see Dworkin, R.).

Taking an overall view, the project of establishing the rule of law as an independent base for the critique and control of state action is put in serious doubt, since interpretation is through-and-through political; and appeals to the rule of law can themselves be moves in a political game, expressions of ideology rather than of higher values. It may be that in the end legal philosophy is faced, today as at its beginnings, with this dilemma: either legal reasoning and moral reasoning have that kind of in-principle objectivity proposed by natural law theory in its rationalist versions, or the theatre of law is simply a theatre presenting endlessly the power-play of rival wills and visions of the good.

Many have sought a third way, not yet with acknowledged success.

LAWS, NATURAL

It is widely supposed that science aims to identify 'natural laws'. But what are laws of nature? How, if at all, do statements of laws differ from 'mere' general truths which include generalizations true only 'accidentally'? Suppose, for example, it happens to be true that all iron spheres (past, present and future) are less than 1 km in diameter. Contrast this with the truth of 'all electrons are negatively charged'. There seems to be a clear intuitive distinction between these two truths, but is there any principled distinction between them that can be drawn and defended?

This has been the traditional focus of philosophical attention concerning laws of nature, and basically two mutually opposed philosophical accounts have been developed. According to the first account, there are real necessities in nature, over and above the regularities that they allegedly produce (whether or not these regularities are held to be observable), and law-statements are descriptions of these necessities. According to the second account, there are no necessities but only regularities (correlations, patterns), and laws are descriptions of regularities (though perhaps not of any regularity but only of the most basic or most general ones). There are significantly different variants of each account; and also positions that altogether deny the existence of general laws (or deny that science should aim to describe them).

Any one of these accounts, if it is ultimately to be coherent and defensible, has to successfully address four interrelated issues: the meaning of a law statement – the semantic issue; the fact to which a law statement refers and which makes it true – the metaphysical issue; the basis on which claims to know a law are justified – the epistemological issue; and the capacity to explain adequately the variety and roles of scientific laws – the explanatory issue.

In attempting this task, each of the available accounts faces its own distinct difficulties. For example, if there are necessities in nature, as the first account claims, how exactly do we identify them: how can we tell which of the inductively confirmed regularities are laws? On the other hand, if there are only regularities, as the second account claims, does this mean that our intuitions and scientific practices are awry and that there really is no distinction between laws and accidental generalizations?

The difficulties facing all extant accounts become even more marked when we face up squarely to the surprisingly wide variety of (putative) laws supplied by current science and to the complexity of the relations between those putative laws and regularities and causes.

C.A. HOOKER

LEBENSPHILOSOPHIE

In its most general sense *Lebensphilosophie* denotes a philosophy which asks after the meaning, value and purpose of life, turning away from purely theoretical knowledge towards the undistorted fullness of lived experience. In the second half of the nineteenth century and the early twentieth century the concept of 'life' assumed a central role in German philosophy. *Lebensphilosophie* typically opposes rigid abstractions with a philosophy based on feeling and intuition, and seeks to establish the priority of 'life' as an all-encompassing whole. The central claim underlying its various manifestations is that life can only be understood from within.

LEGAL POSITIVISM

Legal positivism is the approach in the philosophy of law which treats 'positive law' – law laid down in human societies through human decisions – as a distinct phenomenon, susceptible of analysis and description independently of morality, divine law or mere natural reality. It shares with philosophical positivism the aim of dealing in facts, but these are facts about legality and legal systems. Insistence

on the distinctness of positive law has been integral to the 'rule of law ideal' because of the aim of clear law applied by neutral legal officials. However, debates about positivism have been marred by a degree of conceptual confusion: positivism often appears to mean something different to its supporters and to its enemies, and many attacks are launched against straw men. Consequently, much depends on the definition of legal positivism that is used.

Attempts have been made to put some order into the discussion. Consider, for instance, H.L.A. Hart's list of meanings of legal positivism (which cumulatively count as features of positivism): (1) law as human commands; (2) absence of any necessary connection between law and morals; (3) the study of law as meaning, as distinct from sociology, history and evaluation; (4) the contention that a legal system is a closed system, sufficient in itself to justify legal decisions; (5) non-cognitivism in ethics. Norberto Bobbio's list is shorter and more orderly, but at first sight not too different: legal positivism has been conceived as: (1) a neutral, scientific approach to law; (2) a set of theories depicting the law as the product of the modern state, claiming that the law is a set of positive rules of human origin, and ultimately amounting to a set of statutes, collected in legal systems or orders; (3) an ideology of law that gives a value to positive law as such, implying that it should always be obeyed. However, in this list, unlike Hart's, the 'meanings' cannot be added together, the first and last being incompatible. The connection between the three points is as follows: for positivists the theories of Bobbio's second point (law is made up of rules produced by the state) yield a scientific and value-free approach to law; for the adversaries of legal positivism they yield only ideology, that is hidden value judgments in favour of the power of the state.

The shortest way to understand what is at issue in these abstract discussions is to proceed by contrasting legal positivism with its main critics' approach to law. It is noteworthy that on this point legal realists and natural law theorists, although starting from different and even opposite points of view, agree in concluding that legal positivism is an ideological, covertly evaluative, thesis.

MARIO JORI

LEGAL REALISM

'Legal realism' is the term commonly used to characterize various currents of twentieth-century legal thought which stand opposed to idealism. (Hence, 'realism' in this context ought to be understood not as a body of thought which opposes nominalism, but as an instance of nominalism.) In the Scandinavian countries, legal realism was modelled on Axel Hägerström's critique of idealist metaphysics, and sought ways to account for legal rights and duties without presupposing or postulating the existence of ideal objects or entities. In the USA, legal realism evolved as a critique of the idealism implicit in the vision of the common law which was promoted by C.C. Langdell, first Dean of the Harvard Law School, and in the *laissez-faire* ideology of the late nineteenth- and early twentieth-century Supreme Court. Realist jurisprudential sentiments – primarily as articulated in terms of the so-called indeterminacy critique – continue to bear an influence on late twentieth-century critical legal thought.

NEIL DUXBURY

LEGITIMACY

Legitimacy refers to the rightfulness of a power-holder or system of rule. The term originated in controversies over property and succession, and was used to differentiate children born of a lawful marriage from those who were 'illegitimate'. From thence the term entered political discourse via controversies over the rightful succession to the restored French throne after the Napoleonic period. However, questions about what makes government rightful have been a central issue of philosophical debate since the ancient Greeks, and in this sense the concept, if not the term, 'legitimacy' is as old as political philosophy itself. Its significance lies in the moral, as opposed to merely prudential, grounds for obedience which follow for subjects where power is rightfully acquired and exercised, and in the depth of allegiance which such political authorities can call upon in times of difficulty.

What, then, makes government legitimate? Most thinkers agree that a necessary condition is that power should be acquired and exercised according to established rules, whether these are conventionally or legally defined. However, legal validity cannot be a sufficient condition of legitimacy, since both the rules and the power exercised under them also have to be morally justifiable. Two broad criteria for moral justifiability can be distinguished: (1) political power should derive from a rightful *source* of authority; (2) it should satisfy the rightful *ends* or purposes of government. Most philosophical disputes about legitimacy take

place either within or between these two broad positions; any adequate account of it must embrace both however.

DAVID BEETHAM

LEIBNIZ, GOTTFRIED WILHELM (1646–1716)

Introduction

Leibniz was one of the central figures of seventeenth-century philosophy, indeed, one of the central intellectual figures of his age. Born and educated in Germany, he travelled to Paris in 1672 and quickly entered into its lively intellectual and scientific life, acquainting himself with the most advanced ideas then in circulation. It was there that he invented the infinitesimal calculus, and laid the foundations for the philosophical and scientific programmes that were to occupy him for the rest of his life. He returned to Germany in 1676, entering the service of the House of Hanover where, except for brief absences, he remained until his death. There, along with his court duties, he had time for a wide variety of intellectual activities that eventually gained him an international reputation.

Leibniz's philosophy, particularly his metaphysics, can appear otherworldly and complex. But there are a few simple themes and basic commitments that run through his thought. At root is his philosophical optimism, the commitment that this is the best of all possible worlds, freely created by a rational God who always chooses the best for a good reason. This best of all possible worlds, Leibniz held, is 'the one which is at the same time the simplest in hypotheses and the richest in phenomena' (*Discourse on Metaphysics* §6). For this reason, the world must be governed by a variety of general principles to which Leibniz appealed in his philosophy: there must be a sufficient reason for everything in the world; there are no jumps in nature; there must be exactly the same power in the full cause as there is in the complete effect, among many others. While such principles do not deductively determine the rest of Leibniz's philosophy, they do play a major role in shaping it; they constitute a kind of lens through which he viewed the major philosophical issues of his age.

One such issue concerns the ultimate make-up of the world. Like many of his contemporaries, Leibniz adopted a mechanistic view, according to which everything in the physical world is explicable in terms of the size, shape and motion of the tiny bodies that make up the grosser bodies of experience. But he rejected the idea that this could be the ultimate explanation for things. Behind the mechanistic world of inanimate bodies in motion, Leibniz saw a world of living things and souls – active, genuinely individual, genuinely different from one another, the true atoms of nature, the true reality – which he eventually called monads. At the deepest level, Leibniz's world was made up of an infinity of mind-like entities, each with its own perceptions that change from moment to moment according to an internal programme by way of the faculty of appetition, all in harmony with one another so that they all reflect the same world. While the world of physics is mechanistic, it is merely phenomenal, the confused appearance of a deeper reality. A consequence of this was Leibniz's famous doctrine of pre-established harmony. In contrast to Descartes, for whom mind and body interact, and in contrast to the occasionalists, for whom God is the true cause who brings about motion in the body on the occasion of a volition and a sensation in the mind on the occasion of a stimulation of the appropriate nerves in the body, for Leibniz God created the mind (a single monad) and the body (itself a collection of monads) in perfect harmony with one another so that their mental and physical states would always correspond in the appropriate way.

A second set of metaphysical issues of central concern to Leibniz involves the interlocking questions of necessity, contingency and freedom. In response to contemporaries such as Hobbes and Spinoza, Leibniz tried to find room for contingency and freedom in his world. He argued that even though God is, in a sense, constrained to choose the best, he does so freely. Consequently, the world he created, the best of all possible worlds, exists contingently, and at least some features of it are contingent, those whose contraries are not in themselves impossible. So for example, $2 + 3 = 5$, true in every possible world, is necessary, while 'Adam sins', whose contrary is not impossible, is contingent. But over and above contingency and divine freedom, Leibniz also wanted to make room for human freedom. According to Leibniz, when God created Adam as a part of this best of all possible worlds, he knew that Adam would sin; it is part of the concept of Adam that he sins, part of his internal 'programme' that he will eat the apple, and part of the internal 'programmes' of the monads that make up his body that he will actually eat the apple. But, Leibniz argued, what God builds in is that Adam *freely* chose to sin. God builds into the world the reasons that incline Adam's will without necessitating it, correctly predicting what Adam will do, and building the rest of the world around the consequences of Adam's free actions.

Important as they are, these two concerns constitute only a small portion of Leibniz's thought, even within the domain of philosophy. In psychology, he introduced a distinction between conscious and unconscious perceptions and tried to understand the way in which unconscious perceptions ('*petites perceptions*') in part determine conscious perceptions ('apperceptions'). In epistemology, he is important for his sophisticated version of the innatist hypothesis, and for appreciating the role that a mathematical theory of probability can play in understanding the world. In logic, Leibniz advanced programmes for a new formal logic more powerful than Aristotle's, and for a universal language. In ethics and political thought, he contributed to the seventeenth-century natural law tradition. In natural philosophy, he emphasized the importance of the notion of force and advanced the broadly Cartesian programme of a physics grounded in conservation laws. Outside philosophy he is well known for his work on the calculus. Though he co-discovered it with Newton, it is his notation that is still used, and his version probably had the greater influence in his day. But he was a major contributor to many other fields, including geology, natural history, linguistics and European history. Though he left no real school of followers, he deeply influenced philosophy after his death, particularly in eighteenth-century Germany.

1 Life

Gottfried Wilhelm Leibniz was born in Leipzig on 1 July 1646. He later recalled how his father, who died when he was only six years old, had instilled in him a love of learning. Leibniz started school when he was seven, but more important than his formal education in those years was his reading. He taught himself Latin at an early age in order to be able to read Livy and Calvisius, and because of that was admitted into his late father's extensive library, where he read widely. At fifteen Leibniz entered university, first the University of Leipzig (1661–6), and then the University of Altdorf (1666–7), graduating with degrees in law and in philosophy. The education he received there was conservative, a mixture of traditional Aristotelian school philosophy and Renaissance humanism. Though invited to join the faculty at Altdorf, he chose instead to enter the service of the Elector of Mainz, where he stayed until he was sent to Paris in the spring of 1672 on diplomatic business.

While he had done significant work in a number of areas before going to Paris, including law, theology, mathematics and physics, the trip was crucial to Leibniz's intellectual development. In the later part of the seventeenth century, learned Europe was in the midst of a great intellectual revolution; the older Aristotelian philosophy of the schools was being challenged by a new mechanist philosophy which rejected the form, matter and qualities of the Aristotelian world, replacing them with a world in which everything was to be explained in terms of size, shape and motion. In this new world there was a special emphasis on mathematics, which was increasingly applied to problems in physics in a way quite foreign to Aristotelian philosophy.

Though he had taken an interest in the moderns while in Germany (HOBBES was particularly influential on his early thought), it was only after he reached Paris that Leibniz was able to enter the mainstream of European intellectual life. There he came to know the important mathematician and physicist Christiaan Huygens, who introduced him to new ideas which Leibniz absorbed quickly. In those years, Leibniz laid the foundations of his calculus, his later physics and his philosophy. While there were no publications at the time, many unpublished notes survive, important for understanding the emergence of his mature thought.

Leibniz returned to Germany in December 1676, passing through Holland, where he discussed philosophy with the reclusive SPINOZA. It was then that he first entered the service of the House of Hanover. He served under Duke Johann Friedrich until his death in 1679, under Duke Ernst August from 1680 to 1698, and then, finally, under the Elector Georg Ludwig, who ascended the throne of Great Britain as King George I in 1714. Except for his travels, he remained at Hanover for the rest of his life. There Leibniz undertook a very wide variety of tasks. He served as a mining engineer (unsuccessfully supervising the draining of the silver mines in the Harz Mountains), as head librarian of a large collection of books, as a general advisor and a

diplomat, and was particularly interested in finding ways for the Catholics and the Protestants to reunite. Leibniz was also given the responsibility for writing a history of the House of Hanover. While he collected and published many previously unknown historical documents and published a number of other historical writings, this project barely got off the ground. All that he seems to have completed was a geological history of the region of Lower Saxony, the *Protogaea*. While it proved to be an important work in the history of geology when it was finally published in 1749, it seems not to have pleased Leibniz's employers who had hoped for a history of somewhat more recent times.

Through the rest of his life, Leibniz continued to explore the philosophical, scientific and mathematical questions that interested him from his earliest years. The 1680s and 1690s saw some of his most important writings. In these years, he published his new infinitesimal calculus and a variety of papers outlining his new approach to physics, particularly his new science of dynamics, the science of force and its laws. The *Brevis demonstratio* of 1686 presents for the first time a refutation of Descartes' conservation law, and hints at the foundations of a more adequate physics. The details are developed in his unpublished *Dynamica* (1690), some material from which is published in the *Specimen dynamicum* in 1695, as well as in the numerous answers to attempted refutations of his argument from tenacious Cartesians. In philosophy, Leibniz published his *Meditationes de cognitione, veritate et ideis* (Meditations on Knowledge, Truth and Ideas) in 1684, and in 1686 composed the *Discours de métaphysique* (Discourse on metaphysics), eventually published in 1846; the main arguments from the latter are discussed in a series of letters with the Catholic theologian Antoine ARNAULD, letters Leibniz contemplated publishing in later years. These same themes are found, somewhat transformed, in two important publications in the 1690s, the *Système nouveau de la nature et de la communication des substances* (New system of the nature and the communication of substances) (1695) and the *De ipsa natura* (On nature itself) (1698). In the first decades of the next century, Leibniz continued to be very active. Important in these years were the *Nouveaux essais* (New essays) (1704), a close examination of Locke's *Essay Concerning Human Understanding*, abandoned at Locke's death and unpublished until 1765. But he did publish his *Théodicée* (Theodicy) (1710), a compendium of philosophical and theological ideas involving further development of themes that go far back in his thought. His final philosophical works were short summaries, intended only as brief guides to his work, the *Monadologie* (Monadology) and the *Principes de la nature et de la grâce* (Principles of nature and grace), both of which probably date from 1714.

Throughout these years Leibniz kept up a vast correspondence, including exchanges with Huygens, Johann Bernoulli, Burchardus de Volder and Bartholomaeus Des Bosses, among many others. One exchange is particularly important. Leibniz had been at war with his English counterpart, Sir Isaac Newton, for many years; their rivalry went back to at least the early 1690s, and probably to their first contact in the mid-1670s. The affair was ugly, with accusations of plagiarism regarding the calculus from both sides, and bitter disagreements over the foundations of physics. The rivalry finally resulted, in 1715–16, in a correspondence between Leibniz and Samuel CLARKE, the latter standing in for Newton himself. The exchange was published by Clarke in 1717.

When his employer Georg Ludwig went to London in 1714 to take the throne of Great Britain, Leibniz did not follow. He was out of favour for his failure to make progress on the history of the House of Hanover, as well as for his generally old-fashioned manner. Furthermore, it is likely that Georg feared that the dispute with Newton and the British intellectual establishment would cause difficulties. Whatever the reason, Leibniz remained in Hanover, where he died on 14 November 1716. Though celebrated in his life and considered a universal genius for the breadth of his interests and activities, in death he was virtually ignored, buried with little ceremony in a grave that was to remain unmarked for many years.

2 The programme

Leibniz never wrote a single work, book or article that constitutes a canonical exposition of his thought, preferring the short article or letter where he presents his thought from one or another point of view, often in response to the thought of another (DESCARTES was a favourite target), or in response to questions from a correspondent. Indeed, Leibniz's complex thought seems to resist the kind of comprehensive treatment found in works like Descartes' *Meditations* or Spinoza's *Ethics*. Furthermore, it is only to be expected that Leibniz's beliefs changed over his long career, and from one presentation of his philosophy to another.

Despite its complexity, there are some themes and characteristics that run throughout Leibniz's thought, at least in the mature period that starts after his return from Paris in the late 1670s, the period on which this entry concentrates. (While there was not a radical break from the early years to the later, there is certainly a marked development.) Basic to his thought was his philosophical optimism: this is the

best of all possible worlds, freely created by a rational God, who always chooses the best for a good reason, without any arbitrariness. It is because of our limited understanding that we cannot determine a priori all the general or particular features of this world. This conception of God and his creation shaped Leibniz's philosophy: the world is ultimately both rational and in every way perfect. Furthermore, though Leibniz's philosophical intelligence ranged widely, certain problems were particularly important to him. In an untitled note from the late 1680s he wrote: 'there are two labyrinths of the human mind, one concerning the composition of the continuum, and the other concerning the nature of freedom, and they arise from the same source, infinity' (Leibniz 1989: 95). The labyrinth of the composition of the continuum concerns the ultimate make-up of the world; the labyrinth of freedom concerns how freedom and contingency are possible in the world. The solution to both involves understanding the literally infinite complexity found in the world God created. Leibniz had an opinion about virtually every philosophical and scientific issue of his day, but these two issues consistently drew his attention.

3 God: creation and theodicy

Like many of his contemporaries, Leibniz thought that the existence of God could be proved, and he was particularly attracted by the so-called Ontological Argument, invented by Anselm and revised by Descartes (see God, arguments for the existence of §§2–3). According to the Ontological Argument, as given by Descartes and paraphrased by Leibniz in *Meditations on knowledge, truth and ideas* (1684), 'whatever follows from the idea or definition of anything can be predicated of that thing. Since the most perfect being includes all perfections, among which is existence, existence follows from the idea of God . . . Therefore existence can be predicated of God'. Leibniz's contribution to the argument is the observation that, as it stands, the argument is not valid: 'from this argument we can conclude only that, if God is possible, then it follows that he exists'. For the argument to work, we must establish the self-consistency of the definition of God. But the consistency of the definition of God follows directly from the fact that God 'is without limits, without negation, and consequently without contradiction' (*Monadology* §45). In addition to this version of the ontological argument, Leibniz also used a cosmological argument for the existence of God, arguing from the existence of contingent things in the world, things whose reason lies outside of themselves, to the existence of a necessary being (*De rerum originatione radicali* (On the ultimate origination of things) (1697); *Monadology* §45). Finally, Leibniz argued from the existence of eternal truths: 'Without [God] there would be nothing real in possibles, and not only would nothing exist, but also nothing would be possible' (*Monadology* §43).

In the opening sections of the *Discourse on Metaphysics* (1686: §6), Leibniz argued that 'God has chosen the most perfect world, that is, the one which is at the same time the simplest in hypotheses and the richest in phenomena', a formula that recurs often in his writings. While this is the main account of creation, in other texts, particularly the essay *On the ultimate origination of things*, he argued that 'there is a certain urge for existence or (so to speak) a straining toward existence in possible things or in possibility or essence itself; in a word, essence in and of itself strives for existence' *De rerum originatione radicali* 1697). Leibniz continued: 'From this it is obvious that of the infinite combinations of possibilities and possible series, the one that exists is the one through which the most essence or possibility is brought into existence'. Such an account of creation has the apparent implication that God is not necessary for it, and that creation results from a quasi-mechanistic weighing of possibilities with respect to one another. But Leibniz emphasized that God is the ground of all possibles, and that it is God who ultimately actualizes the possibles that 'win' the 'contest'. The 'striving possibles' account of creation would seem to be a metaphorical way of expressing Leibniz's usual account in terms of God's choice of the best of all possible worlds.

Leibniz's account of creation had a number of important implications. First, against Descartes and Spinoza, it entailed that there is a standard of goodness and perfection that exists independently of God; God creates the world because it is good, a world which is good not just because it is the creation of God (*Discourse* §2). Furthermore, unlike Malebranche, Leibniz held that the world could not have been created better than it is (*Discourse* §§3–4). Leibniz's doctrine of creation can also be read as a direct attack against a conception of God argued by Spinoza. Central to Spinoza's enterprise in the *Ethics* is an attack on the view that God is like us, that he has aims and goals, that he chooses things for a reason, and that he is bound by standards of goodness that exist independently of his will. This anthropomorphic view of God, Spinoza argued, is an illusion, a projection of our own nature onto nature at large (see Spinoza, B. de §4). Against Spinoza, Leibniz presented his own God, who deliberately chooses to create this world for a particular reason, because it is the best of all possible worlds, a reason intelligible to us. It is on this basis

that Leibniz argued against both Descartes and Spinoza for the importance of final causes in nature.

Leibniz's account of creation also addressed the problem of understanding divine justice, in particular, how sin, evil and suffering are possible in a world created by God – the 'theodicy' problem, to use the word coined by Leibniz. His answer was complex, filling many pages in *Theodicy*, the only philosophical book he published in his lifetime. Briefly, his argument was that evil is a necessary and unavoidable consequence of God's having chosen to create the best of all possible worlds. However bad we might think things are in our world, they would be worse in any other.

Leibniz's account of creation was closely connected with a number of his key principles, most prominently the Principle of Sufficient Reason. As he wrote later in the *Monadology* (§53), 'since there is an infinity of possible universes in God's ideas, and since only one of them can exist, there must be a sufficient reason for God's choice, a reason which determines Him towards one thing rather than another'. The Principle of Sufficient Reason entails that the universe is in principle rational and intelligible: God must always act for a reason, and as a consequence, there must be a reason for everything. But the account of creation was also connected with a number of other principles in Leibniz's philosophy (discussed below). In this way one can say that the doctrine of creation underlies all of Leibniz's philosophy. Had we God's intellect, we would be able to derive all of the features of this world directly from its being the best of all possible worlds. As it is, our understanding of God's creation will enable us to fix certain general truths about this world, and set certain bounds on our hypotheses about the way things are.

Leibniz's interest in philosophical theology was not just the interest of a philosopher. He believed that his understanding of truths about God and nature would greatly assist the undertaking of uniting the Catholic and Protestant Churches under the umbrella of the true philosophy.

4 Metaphysics: substance, monad and the problem of the continuum

Leibniz is famous for his claim that he solved the problem of the composition of the continuum. In so far as the continuum (length, area, volume) is divisible, it would seem to be made up out of parts. But what parts could make it up? If the parts are extended (like atoms), then they too are divisible, and we require an account of their composition as well. On the other hand, if the parts are non-extended (like points), then it is difficult to see how they could make up an extended magnitude. Leibniz's solution was this: the mathematical continuum should not be thought of as being *composed* of parts at all; while it has parts, those parts are the result of the division of the whole, and thus are posterior to it. On the other hand, Leibniz claimed, while real physical extensions have parts, there are no physical continua. Physical extended things are at root discrete multitudes whose constituents are substances ('Remarques sur les Objections de M. Foucher' (Remarks on the objections of M. Foucher) 1696; Leibniz to de Volder, 19 January 1706). This raises one of the central problems for Leibniz's philosophy: what are these substances that constitute the metaphysically ultimate constituents of the world?

While there are many paths into his views on substance, Leibniz's critique of Descartes' notion of corporeal substance is a convenient starting place. Descartes held that the essence of body is extension. What this meant is that bodies are geometrical objects made concrete, entities that have no properties that are not grounded in extension. Colour, taste, sound and so on are not themselves in bodies, but are only sensations in minds caused by our interaction with extended substances. While Leibniz as a mechanist agreed with this last claim, he rejected the Cartesian conception of body on which it is based (see Descartes, R. §§8, 11).

Leibniz offered a number of arguments against the Cartesian conception of bodily substance. (1) The notion of extension presupposes some quality that is extended, like whiteness in milk or resistance to new motion in every body, and so is not the kind of thing that by itself could constitute the essence of anything (Leibniz to de Volder, 30 June 1704; 'Note on Cartesian natural philosophy', 1702). (2) In so far as extended things are divisible, they are aggregates made up out of parts. But the reality of the aggregate presupposes some genuine individuals of which the aggregate is composed; no such individuals can be found in Cartesian bodies (Leibniz to Arnauld, 30 April 1687; *Monadology* §§1–3). (3) If the world is full and there are no vacua, and if the world is filled with Cartesian extended substance, then there can be no change in the world. For any supposed change would consist in one portion of body replacing another, identical in every way ('On nature itself'). (4) If body were just extension, then it would be perfectly inert, and would have to be moved by God. If so, then God's creation would be imperfect for lacking creatures which cannot themselves carry out any of God's commands. Indeed, such a world would reduce to Spinoza's world in which finite things are just modes of God ('On nature itself'). Because of arguments like these, Leibniz wanted to take the Cartesian mechanist analysis of body back one step further,

and resolve even extension into something more basic still, a world of substances that are genuinely individual, genuinely active, and which contain properties that distinguish individual substances from one another.

While there are a number of important discussions of the nature of substance in Leibniz's writings, two are especially noteworthy: the one he gave in the *Discourse on Metaphysics* at the start of his mature period, and the one he gave at the very end of his life in the *Monadology.* (There is a third important conception of substance that arises in the dynamical writings, discussed below in connection with his physics.)

Leibniz begins Section 8 of the *Discourse on Metaphysics* by noting that 'it is evident that all true predication has some basis in the nature of things, and that, when a proposition is not an identity, that is, when the predicate is not explicitly contained in the subject, it must be contained in it virtually'. (This principle, which probably derived from Leibniz's logical studies a few years earlier, was closely connected with the Principle of Sufficient Reason in Leibniz's mind; the containment of the concept of the predicate in the concept of the subject constitutes the 'sufficient reason' for the truth of a proposition. This connection with his logic has caused some commentators to see Leibniz's metaphysics as fundamentally logical in its inspiration.) And so, Leibniz claims, 'the subject term must always contain the predicate term, so that one who understands perfectly the notion of the subject would also know that the predicate belongs to it'. He concludes that 'the nature of an individual substance or of a complete being is to have a notion so complete that it is sufficient to contain and to allow us to deduce from it all the predicates of the subject to which this notion is to be attributed'. Since he held that there must be something in the substance itself in virtue of which this complete notion holds of it, he also concludes that at any given time, a substance must contain marks and traces of everything that is true of it, past, present and future – though only God could see them all. (It is not clear whether this committed Leibniz to holding that all properties of a given individual are essential to that individual, making him a kind of 'superessentialist', or whether he takes the weaker position that they are merely internal to the individual, making him a 'superintrinsicalist'. Opinions differ among the commentators.)

In the *Monadology* Leibniz offers a somewhat different characterization of substance. Using the term 'monad' that he adopted to express the notion of an individual substance in the late 1690s, he expounds: 'The monad . . . is nothing but a simple substance that enters into composites – simple, that is, without parts. And there must be simple substances, since there are composites; for the composite is nothing more than a collection, or aggregate, of simples. But where there are no parts, neither extension, nor shape, nor divisibility is possible. These monads are the true atoms of nature and, in brief, the elements of things' (*Monadology* §§1–3). So understood, the Leibnizian world is grounded in non-extended simple substances, whose principal property is non-divisibility and thus, Leibniz inferred, non-extension.

From these basic characterizations of the individual or simple substance (what Leibniz called a 'monad' after the mid-1690s), he inferred a number of important properties. The individual substance or monad is a genuine unity that cannot be split, something explicit in the *Monadology* account, less so on the earlier account in the *Discourse*. Consequently, it can begin only by divine creation, and can end only with divine annihilation; it is naturally ungenerable and incorruptible. On both accounts, individual substances or monads are the sources of all their activity, and cannot be altered or changed by the direct action of others; it is in this sense that Leibniz said that 'monads have no windows through which something can enter or leave' (*Monadology* §7). In the *Discourse* he derives this from the fact that a substance contains within itself all of the grounds of all its properties; there is no need – and no room – for any external causality. In the *Monadology* it is derived directly from the fact that monads are non-extended. The apparent action of one substance on another must be analysed in terms of the relations between the internal states of the one and the internal states of the other (as discussed below). Finally, because of the relations that hold between one substance and another, Leibniz argued that each individual substance or monad reflects the entire world of which it is a part, a thesis closely connected with the hypothesis of pre-established harmony (also discussed below). Though all the individual substances reflect the same one world, they each reflect it from a different point of view, adding the perfection of variety to God's creation (*Discourse* §§9, 15; *Monadology* §§4–7). This conception of harmony can be traced back to the Paris period and, perhaps, to Leibniz's earliest writings on physics.

On Leibniz's view, substances are distinguished from one another by their momentary perceptions, and by the appetitions, the internal source of a substance's activity that lead from one perceptual state to another. In so far as a substance has such appetitions, 'the present is pregnant with the future' (*Monadology* §22). Since there can be no external influences, each monad is created by God with a kind of internal programme, as it were, which determines all of the states that it will take and the

order in which it will take them. Although the Cartesian soul is an important model for the individual substance (Leibniz to de Volder, *c.*1699), there are significant differences. While the momentary states are called perceptions, not all such perceptions are conscious. (Conscious perceptions are said to be 'apperceptions' in Leibniz's terminology, though because nature makes no leaps in this best of all possible worlds, there must be a continuous gradation between the unconscious and the conscious.) In scholastic thought, appetition is the general faculty that leads to change in a substance, of which will (or rational appetite) is a special case in rational souls. For Leibniz, too, not all appetition is rational. For these reasons, he distinguished carefully between rational souls, like ours, and monads with lesser degrees of consciousness and rationality – what he sometimes calls 'bare monads' (*Monadology* §§8–24).

5 Metaphysics: monad, body and corporeal substance

Much of Leibniz's attention was focused on the level of the individual substance or monad, the atom of nature and the building-block of his world, that which in some sense underlies the world of bodies. But in addition to the simple substances, Leibniz often also recognized complex substances, corporeal substances, particularly in the 1680s and 1690s. Corporeal substances are understood on analogy with the human being, a soul (itself an individual substance) united with an organic body. Leibniz often used Aristotelian language to characterize the corporeal substance, calling the soul its form, and the organic body its matter (see ARISTOTLE §§8, 11). The organic body of a corporeal substance is itself made up of corporeal substances, each of which is a soul united to another, smaller organic body, in a sequence of tinier and tinier organisms that goes to infinity, a manifestation of the infinite variety in this best of all possible worlds that God created. Leibniz distinguished corporeal substances from corporeal aggregates, aggregates of animate corporeal substances whose unity is only mental, imposed by the mind, which perceives a group of substances together. While these corporeal substances are ultimately made up of non-extended individual substances, Leibniz's position (at least before 1704) seems to have been that these corporeal substances, as substances, are the genuine individuals whose reality grounds the aggregates that constitute inanimate bodies.

As discussed below, the soul of a corporeal substance is united to its body by virtue of pre-established harmony. However, by 1704, in response to criticism from René-Joseph de Tournemine, Leibniz came to think that this link does not produce genuine unity, and the notion of a corporeal substance becomes problematic for him. While he continued to assert that the physical world is made up of an infinite hierarchy of organisms, after this date he was not so sure that these organisms constitute genuine substances. (Nevertheless, Leibniz always thought that every monad has a body, and cannot exist without one, even if the monad together with its body does not constitute a genuine substance. Even in death the monad has a body, just a body radically smaller than the one it had had in 'life'.) The problem of constructing complex substances from monads led Leibniz in his correspondence with Des Bosses to explore the idea of a *vinculum substantiale*, or a substantial bond. While it is not clear that he ever really endorsed this idea, he does seem to have taken the problem of corporeal substance seriously in that dialogue.

However the issue of corporeal substance is treated, body had a kind of subordinate status for Leibniz. While corporeal substances may be genuine substances, genuinely individual and genuinely active, and thus genuinely real, they are still grounded in non-extended individual substances or monads. And inanimate bodies are inevitably phenomenal, whether the appearance resulting from a multitude of organic corporeal substances, or simply the appearance presented by an infinite multitude of non-extended substances. In this way, one can see Leibniz's philosophy as an inspiration for the distinction between the noumenal and the phenomenal worlds in Kant's philosophy. But in contrast to Kant, who claimed that we cannot know the noumenal world of the thing-in-itself, Leibniz is quite confident that he knows exactly how things are in themselves: they are monads (see KANT, I. §3).

6 Metaphysics: mind, body and harmony

A basic feature of Leibniz's metaphysics was his doctrine that everything reflects the entire world in which it exists. This harmony among things derives from God at creation, who adjusts the perceptions of individual substances or monads to one another in creating a world more perfect by virtue of its variety. And so, despite the fact that individual substances cannot communicate directly with one another, and thus have no real metaphysical causal relations with one another, yet there is an extended sense in which what happens in one substance can be considered the cause of what happens in another. Leibniz wrote: 'The action of one finite substance on another consists only in the increase of the degree of expression together with the diminution of the expression of the other, insofar as God requires them to accommodate themselves to one

another' (*Discourse* §15; compare *Monadology* §52). God, in creating a given substance to perform a particular action at a given time, creates all other substances in such a way as to reflect that action at that time. This is what might be called *physical* causality, as distinct from *metaphysical* causality which Leibniz denied among finite things.

While every monad or substance is related in some way to every other, there is a special relationship between the mind and the body of a living thing, such as the human being: 'Although each created monad represents the whole universe, it more distinctly represents the body which is particularly affected by it, and whose entelechy it constitutes. And just as this body expresses the whole universe through the interconnection of all matter in the plenum (that is, space without empty place), the soul also represents the whole universe by representing this body, which belongs to it in a particular way' (*Monadology* §62; compare *Discourse* §33). In this way, the mind is connected with the world by virtue of the special connection it has with the body; on Leibniz's understanding of causality, mind and body can be the 'physical' causes of changes in one another.

So Leibniz solved to his satisfaction one of the central problems in seventeenth-century metaphysics: the interaction between mind and body. Because of the special harmony between mind and body, just when my body is in the state it would be in if it were pricked by a pin, my mind is programmed to have a sensation of pain. And just when my mind is in the state of willing my arm to raise, my body is in the physical state that would result in the raising of my arm, again not because of any direct causal connection (Leibniz to Arnauld, 28 November/8 December 1686 and 30 April 1687). For that reason, Leibniz wrote: 'According to this system, bodies act as if there were no souls (though this is impossible); and souls act as if there were no bodies; and both act as if each influenced the other' (*Monadology* §81). This is what he originally called the hypothesis of concomitance, but called the hypothesis of pre-established harmony when he published it for the first time in the *New system* (1695).

The view is summarized in an analogy he often used. The mind and the body can be compared to two clocks that keep perfect agreement. One hypothesis to explain their agreement is that of natural influence, the hypothesis that there is some physical connection between the one clock and the other. This corresponds to Descartes' view of mind–body interaction, where there is real causal influence. The second hypothesis is that someone watches over the two clocks and, by tinkering with them, always keeps them in agreement. This corresponds to the occasionalism of many of Descartes' followers, in which mind–body causality is mediated by God who causes sensations in the mind on the occasion of an appropriate bodily state, and actions in the body on the occasion of the appropriate volition in the mind (see OCCASIONALISM). Finally there is the hypothesis that the clocks are so well made that they will always remain in perfect agreement with one another. This corresponds to the hypothesis of pre-established harmony, which Leibniz thought to be the most defensible (Leibniz to Basnage de Beauval 3/13 January 1696).

Leibniz offered a number of arguments directly against occasionalism. He argued, for example, that there must be genuine activity in things themselves because a world of genuinely active things is more perfect than a world of things manipulated by God; indeed, Leibniz claimed, a world of inert things is just the Spinozistic world in which God is the only substance of which other things are modes ('On nature itself'). He also argued that occasionalism posits perpetual miracles, in so far as God is called in to do that which goes beyond the power of things to do by their own nature (Leibniz to Arnauld, 30 April 1687). As noted below, the conception of the physical world that informs Leibniz's dynamics is itself a direct challenge to occasionalism. Nevertheless, Leibniz did share at least one important doctrine with occasionalism: that finite substances have no real causal relations with one another. This doctrine may strike a modern reader as eccentric, but it would have been rather less so for a seventeenth-century reader.

Leibniz often presented the hypothesis of pre-established harmony as a solution to the problem of mind–body interaction. But, at the same time, it allowed Leibniz to reconcile the mechanistic conception of the world with a conception grounded in final causes. He wrote: 'The soul follows its own laws and the body also follows its own; and they agree in virtue of the harmony pre-established between all substances.... Souls act according to the laws of final causes, through appetitions, ends, and means. Bodies act according to the laws of efficient causes or of motions. And these two kingdoms, that of efficient causes and that of final causes, are in harmony with each other' (*Monadology* §§78–9). In more concrete terms, behaviour (raising one's hand, for example) can be explained either in terms of a volition and the harmony God established between mind and body, or purely in terms of the laws of motion, as applied to the physical body. By pre-established harmony, these two explanations will always agree. In this way Leibniz managed to reconcile the dualism of Descartes with the stricter mechanism of Hobbes;

everything in the body can be explained in purely mechanistic terms, while, at the same time, Leibniz could also hold that human beings (and other living organisms) have souls which are the causes of much of their behaviour.

In addition to explaining the interaction between mind and body, when first introduced, Leibniz held that pre-established harmony also explains the union of mind and body, that which makes a single substance out of a mind and the collection of individual substances that constitutes its body (*Discourse* §33). In this way, pre-established harmony provided a central support for Leibniz's account of corporeal substance. Unfortunately, however, it proved inadequate to the task. In May 1703, René-Joseph de Tournemine pointed out that whatever resemblance one might suppose between two clocks, however justly their relations might be considered perfect, one can never say that the clocks are united just because the movements correspond with perfect symmetry. While it does not challenge pre-established harmony as an account of mind–body interaction, the argument is as simple as it is devastating against the somewhat different claim that pre-established harmony accounts for mind–body unity. In consequence, Leibniz came to question the place of complex corporeal substance in his philosophy, as discussed above (see MALEBRANCHE, N.; OCCASIONALISM).

7 Metaphysics: necessity, contingency and freedom

Central to Leibniz's philosophy were a variety of problems concerning necessity, contingency and freedom, problems which arise in a variety of ways from a variety of sources. Spinoza stood behind many of Leibniz's worries. According to Spinoza, everything in the world is necessary and nothing is contingent, so that things could not be other than they are. Indeed, everything that is genuinely possible is actual and if something does not actually exist, it is because it could not. Everything follows from the divine nature, not by choice but by blind necessity. Furthermore, Spinoza argued, everything in the world is determined and what we take to be human freedom is just an illusion. We think that we are free because we are ignorant of the causes outside us that determine us to do what we do.

Other problems came from Leibniz's own views. Some came from Leibniz's principle in accordance with which 'when a proposition is not an identity, that is, when the predicate is not explicitly contained in the subject, it must be contained in it virtually' (*Discourse* §8). If every predicate true of an individual was part of its very concept, how could it fail to be necessary? A closely related problem followed from Leibniz's claim that every individual substance contains everything that can happen to it, past, present and future, which seems to entail that everything was determined from the beginning, and there is no room for the freedom of a creature. Here the problem concerns not necessity and contingency, but determinism and human freedom. Even if it were contingent that a certain creature has a certain built-in history, given that history, there does not appear to be room for freedom.

Leibniz offered a number of approaches to this problem in his writings. His basic response to the Spinozistic attacks on contingency is the claim that God *freely* chose the best of all possible worlds. He wrote in the early 1680s in an essay entitled *De libertate* (On Freedom) 'God produces the best not by necessity but because he wills it' Leibniz [1680–2] 1989: 20). Yet, since God is perfect, it would seem that his nature necessarily determines his will to choose the best.

This led Leibniz directly to another account of contingency. In that same document, he continued by noting that 'things remain possible, even if God does not choose them'. That is, even if God *necessarily* created the best of all possible worlds (a concession Leibniz does not always make), unactualized possibles are still, in and of themselves, possible. The recognition of such unactualized possibles is what brought him back from the precipice of necessitarianism, so Leibniz wrote in another essay from the late 1680s (Leibniz 1989: 21). Elsewhere, he characterized those possibles that God chooses to create as necessary, but only *ex hypothesi*, on the hypothesis that God chose to create them. Though necessary in this limited sense, they are contingent in so far as their contraries are not self-contradictory (*Discourse* §13).

From time to time Leibniz used the kindred notion of compossibility. Two individuals are said to be compossible when they can be actualized at the same time, and are said not to be compossible when they cannot. In this way one can say that a possible world is a maximal set of compossible individuals. The notions of compossibility and incompossibility are not, however, logical notions, taken narrowly. Two individuals may fail to fit in the same possible world because they are logically in contradiction with one another (in a sense that must be specified), or because they fail to harmonize with one another.

Leibniz sometimes also suggested that it is contingent that this particular world is the best of all possible worlds. So, even if God necessarily created the best of all possible worlds, it is still contingent that he creates *this* world. These arguments address the worries that derive from Spinoza's view that God necessarily gave rise to this

world (see SPINOZA, B. de §4). But, as noted previously, there are other more Leibnizian worries to address as well. If in any true proposition the concept of the predicate must be contained in the concept of the subject, how can any truth fail to be necessary? Leibniz gave one kind of answer in the *Discourse on Metaphysics* (§13) where he simply asserts that there are two kinds of conceptual containment. While all predicates are contained in the concept of the subject, some are contained necessarily, and some contingently. But in some documents, probably from the late 1680s, he attempted a different solution. He noted first that in some cases we can demonstrate that the predicate is contained in the subject in a finite number of steps. However, in other cases this cannot be done. 'In contingent truths, even though the predicate is in the subject, this can never be demonstrated, nor can a proposition ever be reduced to an equality or to an identity, but the resolution proceeds to infinity' (Leibniz 1989: 96). To demonstrate a contingent truth, one must show that a given individual with a given property is one among an infinity of individuals in a possible world that is the best among an infinity of other possible worlds, something that cannot be shown in a finite number of steps.

Beyond the question of necessity is the issue of human freedom. Take an individual substance, which contains everything that has happened, is happening and will happen to it. Even if one can establish that the sequence of 'happenings' it contains is contingent, yet by virtue of containing all these happenings, it would seem not to be free to do anything other than what it does. Contingency is thus compatible with strict determinism, which is incompatible with human freedom.

Leibniz's solution was that while God may build certain actions into a given individual, he can build them in as *free* actions: 'God sees for all time that there will be a certain Judas whose notion or idea . . . contains this free and future action' (*Discourse* §30). God does make us with free will, and the ability to choose one thing over another. So, when he chooses to create a given individual with a given life-history, he will include the conditions that will lead that individual to choose one thing over another. But the actual choice is ours, and it is free, Leibniz argued. In this way, 'God inclines our soul without necessitating it' (*Discourse* §30). Furthermore, while we can choose other than the way we do, God in his omniscience can predict what we will actually choose, and build its consequences into our future programme. This divine foreknowledge does not change the character of the events themselves: 'God foresees things as they are and does not change their nature. . . . Thus they are assured but they are not necessary' (*Dialogue effectif sur la liberté de l'homme et sur l'origine du mal* (An actual dialogue on human freedom and on the origin of evil) [1695] 1989: 112). Thus Leibniz had no worse problems on this score than does anyone who believes in divine omniscience.

Leibniz's doctrine did raise a knotty problem about the identity conditions for individuals, however. If all properties of a given individual are programmed in from the beginning, then though some may be contingent, and though some may be free, still, they define the individual as the particular individual that it is; were they different, then we would be dealing with another individual altogether, it would seem. From time to time Leibniz acknowledged that we might want to talk about what might have happened if Judas (*our* Judas, the Judas in *this* possible world) had not renounced Christ (Leibniz–Arnauld Correspondence, May 1686; the specific example at issue there is not Judas, as in the *Discourse*, but Adam). But often Leibniz seemed quite willing to embrace a different view: 'But someone . . . will say, why is it that this man will assuredly commit this sin? The reply is easy: otherwise he would not be this man' (*Discourse* §30). In this way, given that every substance mirrors the entire world in which it finds itself, Leibniz often committed himself to the thesis that a person can belong to only *one* possible world.

8 Epistemology: ideas and sensation

Despite the fact that Leibniz is usually categorized as a continental rationalist, his main interest was not epistemological. At the same time, he did contribute to the discussions of his day on questions relating to ideas and knowledge.

In the *New Essays* (II.1.1), Leibniz defines an idea as follows: 'an idea is an immediate inner object [which] expresses the nature or qualities of things'. He emphasizes that we can think that we have an idea when we do not really have one. So, for example, there can be no idea of a fastest motion because the notion is incoherent. But, he notes, 'At first glance we might seem to have the idea of a fastest motion, for we certainly understand what we say; but yet we certainly have no idea of impossible things'. Mistaking our comprehension of the phrase 'fastest motion' for having a genuine idea can lead us into contradiction in this case. But in other cases, for example in mathematics, where we often use symbols without fixing ideas to them, we often must work symbolically because of the complexity of working directly with ideas themselves. In this sense one can have thought and even reasoning when we do not have ideas in the proper sense. This observation is connected with a distinction Leibniz drew between real and nominal definitions. A

nominal definition is a definition in which one can doubt whether or not the notion defined is genuinely possible; a real definition is one in which the possibility of the notion defined has been established. One can thus say that it is only of real definitions that one can be sure that they correspond to a genuine idea (*Meditations* [1684] 1989: 25–6; *Discourse* §24).

Leibniz was a supporter of innate ideas in a number of senses. First of all, he argued that there are certain particular ideas that are innate to the mind, and do not or cannot come through the senses: 'The ideas of *being*, *possible*, and *same* are so thoroughly innate that they enter into all our thoughts and reasoning, and I regard them as essential to our minds' (*New Essays* I.3.3). He made a similar claim for other notions, such as infinity (*New Essays* II.17.3). In this connection he used his celebrated marble analogy in the preface to the *New Essays*. Ideas and truths are in the mind, he argued, just as the shape of Hercules might already be in the veins of a block of marble, making that shape more likely to emerge when the sculptor begins to hammer on it, even though considerable effort may be required to expose the shape: 'This is how ideas and truths are innate in us – as inclinations, dispositions, tendencies, or natural potentialities'.

Leibniz's metaphysics, however, committed him to a stronger position still, that *every* idea is innate, strictly speaking, since nothing can enter a mind from the outside. He wrote: 'The mind always expresses all its future thoughts and already thinks confusedly about everything it will ever think about distinctly. And nothing can be taught to us whose idea we do not already have in our mind' (*Discourse* §26). But even though all ideas are strictly innate, Leibniz could distinguish between the ideas of sensation that in a certain sense come to us from outside, and the ideas that do not and cannot do so. As with the explication of physical causality in the context of a view in which there can be no real metaphysical causality between finite things, Leibniz could say that 'we receive knowledge from the outside by way of the senses, because some external things contain or express more particularly the reasons that determine our soul to certain thoughts' (*Discourse* §27).

Sensations are distinguished from other notions not only by their causal origin (in Leibniz's somewhat extended sense), but also by the fact that they are confused, in contrast to the distinct notions one uses, say, in mathematics. A notion is distinct when one has 'marks and tests sufficient to distinguish a thing from all other similar' things; distinct notions include number, magnitude, shape and so on. A notion is confused 'when I cannot enumerate one by one marks sufficient for differentiating a thing from others, even though the thing does indeed have such marks and requisites into which its notion can be resolved'. In this sense 'colours, smells, tastes, and other particular objects of the senses' are confused (*Meditations* [1684] 1989: 24). Indeed, they are the confused perception of the geometrical properties of bodies that, on the mechanist programme, ground the perception of sensible qualities. 'When we perceive colours or smells, we certainly have no perception other than that of shapes and of motions, though so very numerous and so very small that our mind cannot distinctly consider each individual one in this, its present state, and thus does not notice that its perception is composed of perceptions of minute shapes and motions alone' (*Meditations* [1684] 1989: 27). Elsewhere Leibniz used the analogy of a wave to understand this phenomenon. When we hear the roar of the ocean, we are actually hearing just a large number of individual waves, lapping on the shore. But since we cannot distinguish the sounds each individual wave makes, we hear it as an undifferentiated roar. This is just the way the confused perception of the corpuscular microstructure of bodies results in our sensation of colour, taste and so on (*New Essays* 1704: preface). In this way Leibniz rejected the claim that the connection between a particular sensation and its mechanical cause is the result of a perfectly arbitrary divine decree; by the Principle of Sufficient Reason, there can be no such arbitrariness in the world (*New Essays* II.8.13 and following, IV.6.7). Thus, it would seem, the distinction between sensations and ideas of the intellect is not a matter of kind, but a matter of degree, degree of distinctness and confusion.

An important part of this account of sensation was Leibniz's doctrine of *petites perceptions* (minute perceptions). Like Descartes, Leibniz believed that we think all the time. However, unlike Descartes, he denied that we are always conscious of what we think. He held that 'at every moment there is in us an infinity of perceptions, unaccompanied by awareness or reflection; that is, of alterations in the soul itself, of which we are unaware because these impressions are either too minute and too numerous, or else too unvarying, so that they are not sufficiently distinctive on their own' (*New Essays* preface). Though we do not apperceive (that is, consciously perceive) each of them individually, these unconscious perceptions have their effects on us. They are what underlie and explain sensation, as suggested earlier. Furthermore, they also have their effect on the conscious choices that we make (*New Essays* II.20.6).

Finally, Leibniz also had a clear position in the debate then raging in the intellectual world over Malebranche's view that we see all things in God,

that is, that ideas do not exist in finite minds, but only in the mind of God, where they are seen by finite intellects without actually being in them (see MALEBRANCHE, N.). Leibniz quite clearly rejected Malebranche's view: 'Even if we were to see everything in God, it would nevertheless be necessary that we also have our own ideas, that is, not little copies of God's, as it were, but affections or modifications of our mind corresponding to that very thing we perceived in God' (*Meditations* [1684] 1989: 27; compare *Discourse* §29).

9 Epistemology: knowledge and probability

In a famous passage of the *Monadology* (§§31–2) Leibniz writes: 'Our reasonings are based on *two great principles*, *that of contradiction*, in virtue of which we judge that which involves a contradiction to be false, and that which is opposed or contradictory to the false to be true, and *that of sufficient reason*, by virtue of which we consider that we can find no true or existent fact, no true assertion, without there being a sufficient reason why it is thus and not otherwise'. These two principles correspond to two different kinds of truths, 'those of *reasoning* and those of *fact*' (*Monadology* §33).

A truth of reason can be known with certainty by a finite demonstration consisting of a finite number of steps containing simple ideas, definitions, axioms and postulates; these truths are necessary and can be known a priori. Sensation can give us particular instances of these truths, but can never attain the kind of universality one finds in necessary truths. As Leibniz wrote in the preface to the *New Essays*: 'necessary truths, such as we find in pure mathematics and particularly in arithmetic and geometry, must have principles whose proof does not depend on instances nor, consequently, on the testimony of the senses, even though without the senses it would never occur to us to think of them'.

While Leibniz agreed with DESCARTES that such truths are innate, he distanced himself from Descartes' appeal to clear and distinct perception. Against those who appeal to Descartes' axiom that 'whatever I clearly and distinctly perceive about a thing is true or is assertable of the thing in question', Leibniz objected that 'this axiom is useless unless we use criteria for the clear and distinct, criteria which we have made explicit' (*Meditations* [1684] 1989: 26–7). While Leibniz agreed with Descartes that we have an innate capacity to recognize these innate truths, as a practical matter, he preferred to constrain the mind by formal rules of logic, unlike Descartes, who rejected formal logic (see §10 below).

Since in all predications, the concept of the predicate is contained in the concept of the subject, all knowledge is in principle a priori; if we only had sufficient knowledge of the subject, we could see everything that is true of it, contained in its complete concept. But this is only possible for God. Humans, incapable of performing the analysis that will reveal the truth a priori must make appeal to the senses in order to discover truths of fact. In fact, Leibniz thought, 'we are all mere Empirics in three fourths of our actions' (*Monadology* §28).

Because of the importance of empirical knowledge, Leibniz called for a genuine logic of probability. The modern theory of probability was born in the 1650s with the correspondence between PASCAL and Fermat, and then with Christiaan Huygens' little treatise, *Tractus de ratiociniis in aleae ludo* (Treatise on reasoning in games of chance) (1657). The theory very quickly developed in the seventeenth century, as new practical applications were quickly found. But Leibniz was not satisfied that it had yet been applied to the most general question of all, the kind of reasoning we do about matters of fact on the basis of sensation when demonstration is impossible. And so, in the *New Essays* (IV.2.14) he called for a new science: 'I maintain that *the study of the degrees of probability* would be very valuable and is still lacking, and that this is a serious shortcoming in our treatises on logic. For when one cannot absolutely settle a question one could still establish the degree of likelihood on the evidence, and so one can judge rationally which side is the most plausible.... I suspect that the establishment of an *art of estimating likelihoods* would be more useful than a good proportion of our demonstrative sciences, and I have more than once contemplated it'. But even though Leibniz may have contemplated it, he himself never made a serious attempt to develop the logic of probability that he called for here. However, his call was heard by David HUME, who saw his *Treatise* as, in part, answering Leibniz's challenge.

10 Logic and language

From his youth, Leibniz dreamed of constructing a perfect, logical language, 'a certain alphabet of human thoughts that, through the combination of the letters of this alphabet and through the analysis of the words produced from them, all things can both be discovered and judged'. This programme, which Leibniz called the 'universal characteristic', gets its first expression in the very early work, *Dissertatio de arte combinatoria* (Dissertation on the art of combinations) (1666). But it is most fully developed later, from the mid-1670s into the 1680s.

Leibniz's programme had two parts. First, one must assign characteristic numbers to all concepts

that show how they are built up out of simpler concepts. Leibniz tried a number of schemes for this, but one strategy was to assign simple concepts prime numbers, and then assign complex concepts the product of the characteristic numbers of its constituent simple concepts. The second part of the programme was then to find simple mechanical rules for the truth of propositions in terms of the characteristic numbers of their constituent concepts. Leibniz's fundamental rule in his Universal Characteristic was the principle discussed above in connection with his metaphysics: a predicate is true of a subject if and only if its concept is contained in the concept of the subject. If the concepts in question can be expressed numerically, then Leibniz thought that the rule can be given a mathematical form as well, and the truth of a proposition could be established by a simple arithmetical calculation. Leibniz's project in these writings was to show how this basic intuition about truth could be extended to propositions that are not in simple subject-predicate form. He also sought to extend the programme to formalize the validity of the standard inferences in Aristotelian logic. Even if he could not assign definite characteristic numbers to particular concepts, Leibniz tried to show that for certain configurations of premises and conclusions, if the premises are true (on his definition of truth), then so too must be the conclusion.

The programme was very ambitious; it if were successful, it would allow the truth or falsity of any proposition, necessary or contingent, to be determined by calculation alone. However, it soon dawned on Leibniz that the idea of finding all the conceptual dependencies necessary to express the contents of notions numerically was utopian in the extreme, particularly given the doctrine of infinite analysis of contingent truths Leibniz came to in the late 1680s. This realization still left in place the more modest programme of validating patterns of inference. But even this more modest programme turned out to be beyond Leibniz's ability to bring to completion, and after the early 1690s he seems to have given up trying to make it work, although he returned to it from time to time.

But even though this particular programme collapsed, the idea of formalism was quite basic to Leibniz's thought. Part of the reaction against the Aristotelian philosophy of the schools was an attack on formal logic. Descartes, Locke and others in the seventeenth century argued that we all have an innate ability to recognize truth, what was often called intuition, and that we should cultivate that capacity, and not waste our time learning formal rules. While Leibniz certainly agreed that we do have the innate capacity to grasp certain truths, he still thought that formalism is very important (Leibniz to Elisabeth of Bohemia, 1678). Much of our reasoning is 'blind' or symbolic, Leibniz thought, conducted through the manipulation of symbols without having a direct hold on the ideas that underlie the symbols. For that reason we must have clear and unambiguous symbol systems, and strict rules for manipulating them (*Meditations*).

This view is evident in the papers on the Universal Characteristic. But it also underlies another project of the same period, the differential and integral calculus, one of Leibniz's greatest accomplishments, worked out by 1676 and made public from 1684. Though others before him had solved many of the particular problems his calculus could solve, problems relating to tangents, areas, volumes and so on, Leibniz invented a simple notation, still used in the calculus ('d' to represent the operation of differentiation, and '∫' to represent the operation of infinite summation (integration)), and worked out a collection of simple rules for applying these operations to equations of different kinds. In this way, Leibniz was able to produce simple algorithms for solving difficult geometrical problems 'blindly', by manipulating certain symbols in accordance with simple rules.

Another issue closely connected with Leibniz's logic is that of relations. In the *Primae veritates* (First truths) [1689] 1989: 32) Leibniz wrote: '*There are no purely extrinsic denominations* [that is, purely relational properties], denominations which have absolutely no foundation in the very thing denominated.... And consequently, whenever the denomination of a thing is changed, there must be a variation in the thing itself'. In this way, all relations must be, in some sense, grounded in the non-relational properties of things. But it is not clear that Leibniz held that relations had to be reducible to non-relational predicates of things. In one example he gives, he paraphrased 'Paris is the lover of Helen' by the following proposition: 'Paris loves, and by that very fact [*eo ipso*] Helen is loved'. While this certainly relates the relation '*A* loves *B*' to two propositions that have the form of simple subject-predicate propositions ('*A* loves' and '*B* is loved'), it should be noted that the predicates in question ('loves' and 'is loved') would seem to be implicitly relational; whether this is an accidental feature of the example Leibniz chose or a clue to Leibniz's views is a question of some dispute. Furthermore, it is important not to ignore that which connects the two propositions ('and by that very fact'), without which one cannot say that the two non-relational propositions capture the relation '*A* loves *B*'. Other texts suggest that individuals properly speaking have non-relational properties, and that the relations between things are something imposed by the mind onto the world: 'My judgement about relations is

that paternity in David is one thing, sonship in Solomon another, but that the relation common to both is a merely mental thing whose basis is the modifications of the individuals' (Leibniz to Des Bosses, 21 April 1714). But in saying that the relations between individuals are 'merely mental', Leibniz does not necessarily mean to dismiss them. He wrote: 'God not only sees individual monads and the modifications of every monad whatsoever, but he also sees their relations, and in this consists the reality of relations and of truth' (letter to Des Bosses, 5 February 1712).

In addition to formal languages, Leibniz was also keenly interested in the study of natural languages. Like many of his contemporaries, he was interested in the controversies over the question of the Adamic language, the language spoken in Eden and from which all modern languages supposedly derive. This, among other motivations, led him to the empirical study of different languages and the etymology of words.

11 Natural philosophy

Leibniz is read today largely for his philosophical writings. But in his day, he was, if anything, better known for his work in mathematics and natural philosophy. Like many of his contemporaries, Leibniz was a mechanist. Indeed, he was in a sense a much stricter mechanist than the Cartesians. Because of his doctrine of pre-established harmony (see §6 above), one can always give a purely mechanistic explanation of any physical phenomenon, even in humans, unlike in the Cartesian system, where causal interaction between mind and body, direct or occasional, can disrupt the laws governing the body. However, Leibniz's version of the mechanist programme departed significantly from other main versions of the programme of his day, particularly the Cartesian version.

Leibniz rejected the Cartesian analysis of body as extended substance (see §4 above). Instead, he argued that we must go to a deeper level of analysis, behind the extension of bodies to the substances that are the ultimate constituents of reality. Below the level of inanimate extension there are tiny organisms, souls joined to organic bodies which Leibniz, in at least one period of his thought, considered genuine corporeal substances. At a deeper level still there are the non-extended simple substances or monads that ground the reality of corporeal substances. On this view, the extended bodies of the Cartesian world are phenomena, aggregates of substances that are unified by virtue of being confusedly perceived together.

Leibniz also rejected Descartes' central law of nature. For Descartes, God conserves the same quantity of motion in the world, the size times the speed of bodies taken together (see DESCARTES, R. §11). But Leibniz argued that what is conserved is not bulk times speed, but bulk times the *square* of speed, mv^2, a quantity associated with what he called *vis viva* or living force. To defend this view, he used a cluster of a posteriori arguments which assumed the Galilean law of free-fall (the distance fallen is proportional to the square of the speed acquired in free-fall) together with the Principle of the Equality of Cause and Effect, in accordance with which there is always as much ability to do work in the cause as there is in the full effect. Leibniz showed that, on these assumptions, the Cartesian conservation law entails that the ability to do work can either be gained or lost in certain circumstances, whereas on the assumption of the conservation of mv^2, this does not happen. Leibniz used this strategy in the *Brevis demonstratio* (Brief Demonstration of a Notable Error of Descartes) (1686), where he first published this result. In addition, he offered an a priori argument in which, arguing from certain abstract notions of motion, action and effect, together with an intuitive principle of the conservation of effect, he reached the same conclusion (*Discourse* §17; *Dynamics* preliminary specimen). This challenge to Descartes' conservation law elicited numerous responses from the Cartesian community in what came to be called the *vis viva* controversy.

Leibniz saw the replacement of the conservation of the quantity of motion by the conservation of mv^2 as leading us to introduce into the world of physics something over and above the purely geometrical qualities of size, shape and motion that pertain to the extended substance of the Cartesians. This something is what he called force, the new science of which he named dynamics. While force can cause motion and is sometimes manifested in motion, Leibniz carefully distinguished the two. In emphasizing the distinction between force and motion, Leibniz was rejecting not only the Cartesian tradition, but his own early physics where, following Hobbes, he identified force with motion.

Leibniz recognized a variety of different kinds of forces in nature. At the most fundamental level, he distinguished between primitive and derivative forces, and between active and passive forces. Thus, in all, there are four basic kinds of force: primitive and derivative active force, and primitive and derivative passive force. Active force is of two sorts, living force (*vis viva*), which is associated with bodies actually in motion (a ball moving with a definite velocity), and dead force, which is associated with the instantaneous push from which actual motion results, as in gravitation or elasticity. Passive force, on the other hand, is the force that

arises in reaction to the active force of another body. It also has two varieties, impenetrability (the force that prevents two bodies from occupying the same place at the same time) and resistance (the force that opposes new motion). The distinction between primitive and derivative force is quite different. Primitive force, active and passive, is the metaphysical ground of activity and passivity, that in a body by virtue of which it is capable of acting (doing work) or resisting. Derivative forces, for Leibniz, were particular states of activity and passivity that exist in a body at a particular time. In this way, primitive force is not a measurable quantity, but something in body that grounds the reality of the derivative forces, which are measurable quantities.

This notion of force was linked directly to Leibniz's notion of corporeal substance: 'Primitive active force, which Aristotle calls first entelechy and one commonly calls the form of a substance, is another natural principle which, together with matter or passive force, completes a corporeal substance' ('Note on Cartesian natural philosophy' [1702] 1989: 252). At least in the 1680s and 1690s, when Leibniz recognized corporeal substances, the primitive forces seem to have been the form and matter of the corporeal substances that ground the reality of the physical world. Derivative forces would then be interpreted as the momentary states of these corporeal substances. The position is somewhat different after Leibniz began to doubt the reality of corporeal substance (see §5 above). Then, he wrote, 'I relegate derivative forces to the phenomena, but I think that it is obvious that primitive forces can be nothing but the internal strivings of simple substances, strivings by means of which they pass from perception to perception in accordance with a certain law of their nature' (Leibniz to de Volder, 1704 or 1705). In this way, the dynamics can be regarded as another perspective on the same entities discussed in Leibniz's more metaphysical writings.

Leibniz held that these forces (or better, the motion that they cause) obey rigorous mathematical laws. These laws include the conservation of living force, mv^2, virtually equivalent to the modern law of the conservation of kinetic energy, and the conservation of bulk times the velocity (a vector quantity), *mv*, identical to the modern law of the conservation of momentum. (Because Leibniz's conservation of *mv* involved the directionality of the motion, it is distinct from the Cartesian conservation of quantity of motion, which Leibniz rejected.) While he disagreed with Descartes about the specific contents of the laws, he can be seen as advancing the Cartesian programme of building a physics grounded in mathematically expressible conservation laws. But even though Leibniz's laws are expressible in mathematical terms, they – like the forces that they govern – are grounded in certain metaphysical principles that are imposed on the world by the wisdom of God: 'Although the particular phenomena of nature can be explained mathematically or mechanically... nevertheless the general principles of corporeal nature and of mechanics itself are more metaphysical than geometrical' (*Discourse* §18).

One such general metaphysical principle was noted in connection with the establishment of Leibniz's conservation law, the Principle of the Equality of Cause and Effect. But there were others as well. Leibniz made frequent use of the Principle of Continuity, according to which nothing happens through a leap. Leibniz used this principle to refute Descartes' laws of impact, where small changes in the initial conditions (say the comparative sizes of the bodies in question, or their motion) can result in radically different results. This principle was also used to refute atomism. If there are perfectly hard atoms, not made up of smaller separable parts, then in collision their motion would change instantaneously at the moment of impact. So, Leibniz concluded, there cannot be any such atoms in nature. Indeed, he used this argument to conclude that every body, no matter how small, is elastic. Leibniz also made appeal to the Principle of Plenitude to argue that there can be no vacuum or empty space in the world, since if God *can* create something consistent with his other creations, he *must* do so. Finally, as seen below, Leibniz used the Principle of Sufficient Reason in connection with his relativistic account of space and time.

The very fact that the world is the product of divine wisdom allowed Leibniz to appeal to final causes in his physics. This differentiates him from both Descartes and Spinoza, both of whom rejected final causes. Leibniz agreed with both that everything in nature can be explained through efficient cause alone – that is, through the laws of motion alone. But often, particularly in optics, it is much easier to solve problems by appealing to God's wisdom, and discovering the way in which a most perfect being would have created his universe (*Discourse* §22; *Specimen of dynamics* 1695: part I). However, the appeal to final cause only supplements the understanding of nature by efficient causes, and does not replace it. It is another manifestation of divine harmony that the explanations by efficient causes and by final causes always coincides: 'In general we must hold that everything in the world can be explained in two ways: through the kingdom of power, that is, through efficient causes, and through the kingdom of wisdom, that is, through final causes.... These two kingdoms everywhere

interpenetrate each other...so that the greatest obtains in the kingdom of power at the same time as the best in the kingdom of wisdom' ((*Specimen of dynamics* [1695: part I] 1989: 126–7).

So far we have been discussing Leibniz's work in relation to that of other mechanists, particularly those of the Cartesian school. But it is also important to understand Leibniz's relations with another contemporary and often bitter rival, Isaac Newton.

In opposition to Newton, who held an absolutist conception of place and space, Leibniz argued that space is 'only relations or order or orders of coexistence, both for the actually existing thing and for the possible thing one can put in its place' (*Remarks on Foucher* [1696] 1989: 146). If Newton were right, Leibniz argued, and there was absolute space, then God could create a world in which what is currently east and west are exactly reversed, for example. But if so, by the Principle of Sufficient Reason, then God could have no reason to create one such world over another. Given that he did, he cannot have been faced with such a choice. Leibniz concludes that the two purported Newtonian worlds are really just one world, a world in which space is just constituted by the relations between things (Leibniz to Clarke, 3rd paper §5). Newton's absolutist account of space was supposed to ground an absolutist account of motion as well. For Newton, motion was the change of place of a body with respect to absolute space. Leibniz rejected this too, arguing that motion is a completely relativistic notion, a matter of the relation between bodies over time and that alone (*Specimen of dynamics* part I; Leibniz to Huygens, 12/22 June 1694).

Leibniz also rejected Newton's theory of universal gravitation. He read Newton as holding that gravity is an essential property of matter as such, and he was appalled. For Leibniz, all change in body had to happen through the intermediary of contact and collision; the idea of action at a distance that seemed to underlie Newton's theory of universal gravitation was an intellectual disaster, a treasonable abandonment of the new mechanical philosophy and a return to the worst abuses of the schoolmen. Leibniz, whose early mechanism seemed so radical at the time, could not adjust to the new Newtonian philosophy, soon to take over the intellectual world (see CLARKE, S.; NEWTON, I.).

While the emphasis here has been on the aspects of Leibniz's work in physics most relevant to his philosophical programme, he was much more widely interested in the natural world. He left notes on engineering problems, on chemistry, on geology and on curious observations in natural history including the report of a talking dog, and a goat with an odd hairstyle.

12 Ethics and political thought

Although Leibniz's ethical and political writings are not widely read today, they constitute an important part of his corpus, unsurprising, given Leibniz's own involvement in politics. Leibniz's ethical and political thought, squarely within the natural law tradition, was based on the notions of justice, charity and virtue (see NATURAL LAW). Leibniz wrote: 'Charity is a universal benevolence, and benevolence the habit of loving or of willing the good. Love then signifies rejoicing in the happiness of another, or, what is the same thing, converting the happiness of another into one's own' (*Codex Iuris Gentium Diplomaticus* (The diplomatic code of the law of nations) 1693: introduction). In a note on felicity (Leibniz *c.*1694–8), he connected justice, wisdom, and virtue to charity: 'Virtue is the habit of acting according to wisdom.... Wisdom is the science of felicity, [and] is what must be studied above all things.... To love is to find pleasure in the perfection of another. Justice is charity or a habit of loving conformed to wisdom. Thus when one is inclined to justice, one tries to procure good for everybody, so far as one can, reasonably, but in proportion to the needs and merits of each'.

For Leibniz, human justice is the same as God's justice, though, of course, less perfect. Leibniz wrote in the *Monita quaedam ad S. Puffendorfii principia* (Observations on the principles of Pufendorf) (1706): 'In the science of law...it is best to derive human justice, as from a spring, from the divine, to make it complete. Surely the idea of the just, no less than that of the true and the good, relates to God, and above all to God, who is the measure of all things'. Similarly, Leibniz wrote in *Méditation sur la notion commune de la justice* (Meditation on the common concept of justice) (1702–3) that 'as soon as [the concept of justice] is founded on God or on the imitation of God, it becomes universal justice, and contains all the virtues'.

In so far as charity is defined in terms of universal love and benevolence, justice is something quite distinct from power. This is true even for God. 'Justice, indeed, would not be an essential attribute of God, if He himself established justice and law by His free will'. In this sense, God is as bound by the eternal laws of justice as he is bound by truths of reason: 'Justice follows certain rules of equality and of proportion [which are] no less founded in the immutable nature of things, and in the divine ideas, than are the principles of arithmetic and of geometry' (*Observations on Pufendorf* 1706). (Here, perhaps is the origin of the theodicy problem for Leibniz: if God is bound by the same ideal of justice that binds us, then we must show how the works of

the all-perfect creator can be seen to conform to that ideal.) So, too, are we bound by a standard of justice that exists independently of our wills.

Leibniz recognized three degrees of justice. The lowest, a minimal sort of justice, is simply not to harm others. The second degree is to give each their due, what it is that is owed to them. The highest, though, is to behave with genuine beneficence toward others, and to do that which will promote their happiness; this is what Leibniz calls piety (Leibniz to Coste, 4 July 1706: appendix).

Leibniz's conception of justice as the charity of the wise also placed virtue and obligation outside of the scope of a contract. For Hobbes, for example, the notion of justice arises from a contract that we make with one another in forming a society, and the notion of justice has no applicability outside that framework. Commenting on Shaftesbury in 1712, Leibniz wrote: 'Our illustrious author refutes with reason . . . those who believe that there is no obligation at all in the state of nature, and outside government; for obligations by pacts having to form the right of government itself, according to the author of these principles, it is manifest that the obligation is anterior to the government which it must form' (Leibniz 1988: 196). Indeed, he noted, there are societies, among the native Americans for example, in which the sovereign thought necessary by Hobbes is altogether absent: 'entire peoples can be without magistrates and without quarrels, and . . . as a result men are neither taken far enough by their natural goodness nor forced by their wickedness to provide themselves with a government and to renounce their liberty'. In people sufficiently wise, then, justice and charity are sufficient to hold society together, without the need of a contract.

But Leibniz was a practical politician, as well as a theorist of politics. He generally worked for a Europe unified under the leadership of a unified church, a Christian Europe in which there are no conflicts between different Christian states. This, in part, is what was behind his plan for the reunification of the Catholics and the Protestants. It was also behind his attempt, as early as 1671, to persuade the French to attack Egypt, a non-Christian country, rather than to invade the Netherlands. In practice, however, Leibniz was an opponent of French expansionism under Louis XIV (as much as he was an admirer of French culture), and a supporter of a union of Protestant countries in Northern Europe (his *Mars Christianissimus* (1684) was a brilliant satire directed against Louis XIV's foreign policy). He was also an active participant in the successful campaign in support of the claim of the House of Hanover for the throne of England.

13 The Leibnizian tradition

It is important to remember when considering Leibniz's influence that much of what we now know of Leibniz's writings was unknown to his readers for many years after his death. The full dimensions of Leibniz's thought emerged only slowly, as new texts came to light. Indeed, there is still no complete edition of his work.

At the time of his death, and in the decade afterwards, only a small selection of Leibniz's texts was available. There were a fair number of publications in mathematics and physics, some legal writings and some documents collected in connection with his unfinished history of the house of Hanover. In philosophy, however, there were only a few essays. During his lifetime, Leibniz had published *Meditations on Knowledge, Truth, and Ideas* (1684), the *New System* (1695), *On Nature Itself* (1698) and the *Theodicy* (1710). The Leibniz–Clarke correspondence was published soon after his death, and a Latin version of the *Monadology* appeared in 1721. On the other hand, the *New Essays* did not appear until 1765, and works that we now consider central, such as the *Discourse on Metaphysics*, did not appear until 1846. Many of his philosophical writings and correspondence had to await the monumental edition of C.I. Gerhardt, which appeared between 1875 and 1890. Many texts have yet to appear.

Despite the relative paucity of his available writings, Leibniz was much read and debated in the eighteenth century. One of his early supporters was the German professor Christian WOLFF who had corresponded with Leibniz during his life. He composed numerous volumes expounding a Leibnizian philosophy in an ordered and orderly way. Wolff's systematic philosophy made it ideal for the academy, and his ideas were widely influential. But there were opponents, particularly a group of pietist theologians at the University of Halle, but others as well, including Maupertuis, Crusius, CONDILLAC and, most famously, VOLTAIRE, who made Leibniz into the comical Dr Pangloss of his *Candide*. KANT received his philosophical education in the atmosphere of this debate between the Leibnizians and the anti-Leibnizians in the German intellectual world. His philosophy, both pre-critical and critical, shows the marks of his knowledge of Leibniz's writings.

LESSING, GOTTHOLD EPHRAIM (1729–81)

Gotthold Ephraim Lessing occupies a central place in eighteenth-century European belles-lettres. He was a significant religious and theological thinker whose work puzzled his contemporaries and still provokes debate. He has been variously called a deist, a concealed theist, a Spinozist–pantheist, a panentheist, and an atheist. He was a significant dramatist whose major works include *Minna von Barnhelm*, known as the first modern German comedy, and *Nathan the Wise*, which places Lessing in the tradition of eighteenth-century toleration and humanism. He was an active promoter of the contemporary German theatre and an influential drama critic and theorist. He had broad classical and antiquarian interests. And he has some claims to being one of the early developers, if not a founding father, of the discipline of philosophical aesthetics.

Philosophically, Lessing belongs to the tradition of G.W. von Leibniz and Christian Wolff and was familiar with the post-Wolffian aesthetics being developed by Alexander Baumgarten and his follower Georg Friedrich Meier. Most importantly, perhaps, Lessing was acquainted with Moses Mendelssohn, to whose work his own philosophical writings bear many similarities and who read and commented on Lessing's aesthetic writings. But Lessing cannot be identified with any of these philosophical sources and influences. His work retains many rationalist presuppositions, but Lessing also consciously sought a more inductive approach. He adhered to neoclassical standards with respect to beauty and the application of rules of art, but severely qualified those standards by justifying them empirically and appealing to emotional effects rather than to ideal forms or Cartesian clarity. Lessing's aesthetics must be inferred from his work, particularly from his *Laocoon*, some of the numbers of the *Hamburg Dramaturgy*, and to a lesser extent from short works such as 'How the Ancients Represented Death' and the letter of 26 May 1769 to Friedrich Nikolai. What emerges is a sometimes inconsistent and fragmentary aesthetic, which one might describe as a critical rationalism.

DABNEY TOWNSEND

LEUCIPPUS (5th century BC)

The early Greek philosopher Leucippus was the founder of atomism. Virtually nothing is known of his life, and his very existence was disputed in antiquity, but his role as the originator of atomism is firmly attested by Aristotle and Theophrastus, although the evidence does not allow any distinction between his doctrines and those of his more celebrated successor Democritus. He wrote a comprehensive account of the universe, the *Great World-System*. The single surviving quotation from his work asserts universal determinism.

C.C.W. TAYLOR

LEVINAS, EMMANUEL (1906–95)

In the 1930s Levinas helped to introduce the phenomenological philosophy of Husserl and Heidegger to the French. Subsequently his work attained classic status in its own right for his attempt to explore the meaning of ethics from a phenomenological starting-point. In *Totalité et infini* (1961) (*Totality and Infinity*, 1969) Levinas locates the basis of ethics in the face-to-face relation where the Other puts me in question. My obligations to the Other are not contracted by me. They not only precede any debts I incur, but also go beyond anything I could possibly satisfy. In later works, most notably *Autrement qu'être* (1974) (*Otherwise than Being*, 1981) Levinas explores further the preconditions of this account, most especially by investigating the I that was said to be put in question in the encounter with the Other. In analyses that stretch phenomenology to its limits and beyond, Levinas finds alterity within the self.

ROBERT BERNASCONI

LEWIS, CLARENCE IRVING (1883–1964)

The American philosopher C.I. Lewis held that in all knowledge there are two elements: that which is presented to sense and the construction or interpretation which represents the creative activity of the mind. Contrary to Kant, Lewis claimed that what is fixed and unalterable is not the structure that we bring to the sensibly presented, but rather the

sensibly presented itself. The categories that mind imposes do not limit experience; they determine the interpretation we place upon experience, and if too much of experience eludes our categorizations, new ones should be established. It is pragmatically necessary that we create interpretive structures which will work in getting us around in sensory experience. This important and novel doctrine, Lewis' 'pragmatic a priori', emerged through the development of ideas which took root during his study of logic. The problems of choosing among alternative logics led him to assert the need for pragmatic criteria. The way we conceptually structure or categorize experience answers to pragmatic criteria of purposes, intents and interests. Only within a context defined by a priori categorizations can empirical judgments be made. These empirical judgments proceed from apprehensions of the sensibly presented to assertions of objectivities. Moral judgments require both judgments of good and decisions of right. Judgments of value are tied to qualitative satisfactions disclosed in experience and are empirical claims. Decisions about the morally right are based on imperatives of reason.

PETER VAN INWAGEN

LIBER DE CAUSIS

The *Liber de causis* (Book of Causes) is a short treatise on Neoplatonist metaphysics, composed in Arabic by an unknown author probably in the ninth century in Baghdad. Through its twelfth-century Latin translation, it greatly influenced mature medieval philosophy in the West.

Drawing heavily on the Greek Neoplatonist Proclus, the *Liber de causis* represents a development of late Neoplatonism along two lines. On the one hand, the author modifies and simplifies Proclus' theory of causes to accord more closely with the three-part division of ultimate causes advanced by the founder of Neoplatonism, Plotinus. On the other hand, the author introduces some of the metaphysical principles of Qu'ranic or biblical monotheism. The result is a metaphysically provocative reinterpretation of Neoplatonist thought which, because it seemed to accommodate Platonist philosophy to the medieval worldview, made the *Liber de causis* a natural source text for medieval philosophers.

HANNES JARKA-SELLERS

LIBERALISM

Introduction

Liberal political philosophy explores the foundations of the principles most commonly associated with liberal politics: freedom, toleration, individual rights, constitutional democracy and the rule of law. Liberals hold that political organizations are justified by the contribution they make to the interests of individuals, interests which can be understood apart from the idea of society and politics. They reject both the view that cultures, communities and states are ends in themselves, and the view that social and political organizations should aim to transform or perfect human nature. People have purposes of their own to pursue, either economic or spiritual (or both). Since those purposes do not naturally harmonize with one another, a framework of rules may be necessary so that individuals know what they can count on for their own purposes and what they must concede to the purposes of others. The challenge for political philosophy, then, is to design a social framework that provides this security and predictability, but represents at the same time a safe and reasonable compromise among the disparate demands of individuals.

1 Liberal politics

In politics, the term 'liberalism' denotes a family of positions centred around constitutional democracy, the rule of law, political and intellectual freedom, toleration in religion, morals and lifestyle, opposition

to racial and sexual discrimination, and respect for the rights of the individual.

Often these positions are associated with a suspicion of state authority, with a view that the powers of government should be constrained if not minimized, and with a confidence in the ability of individuals to organize themselves on the basis of the market, the free interplay of ideas and the loose and informal associations of civil society. Liberal support for democracy is therefore sometimes qualified by fear of 'the tyranny of the majority' and by apprehensions about the extent and intrusiveness of the power that a populist state is capable of exercising.

These attitudes are not, however, characteristic of all forms of liberalism. In Britain, in the late nineteenth and early twentieth century, a group of thinkers known as the New Liberals made a case against *laissez-faire* and in favour of state intervention in social, economic and cultural life. The New Liberals, who included T.H. GREEN and L.T. Hobhouse, saw individual liberty as something to be achieved under favourable social circumstances. The poverty, squalor and ignorance in which most people lived made it impossible in their view for freedom and individuality to flourish, and the New Liberals believed that these conditions could only be ameliorated through collective action coordinated by a strong welfare-oriented interventionist state.

In the USA, since the early part of the twentieth century, the term 'liberalism' has been associated with 'progressive' economic reform, a commitment to the modest redistribution of income that takes place in a welfare state, a suspicion of business and an abiding faith in the legal regulation of economic affairs. The more *laissez-faire* version of liberalism is called 'conservatism' in the USA, and Europeans are often disconcerted to hear 'liberal' used there as label for positions that they themselves would describe as left-wing or moderately socialist.

This is not just terminological confusion. Those in the USA who call themselves 'liberals' do also hold the positions outlined at the beginning of this article, and their disagreement with 'conservative' opponents is partly a live and unresolved issue about the implications of traditional liberal premises in so far as social and economic policy is concerned. Does individual freedom require private ownership? Is poverty compatible with liberty? Can civil and political rights be equal if economic power is not? Liberalism is a family of positions, and these remain important family disputes.

2 Political philosophy

In philosophy, 'liberalism' is not just the name of a loosely organized and quarrelsome family of substantive political opinions. It refers also to a heritage of abstract thought about human nature, agency, freedom, and value, and their bearing on the functions and origins of political and legal institutions.

That heritage takes its rise in early modern English political philosophy – most notably in the work of Thomas HOBBES and John LOCKE (§10). It is also the political philosophy of the European Enlightenment, represented in its most philosophically articulate form in the writings of Jean-Jacques ROUSSEAU, François-Marie Arouet VOLTAIRE, Henri-Benjamin Constant de Rebecque and, a little later, Immanuel KANT. In the nineteenth century, philosophical liberalism is represented, first, in the utilitarian theories of BENTHAM and J.S. MILL, and later in the 'Idealism' of T.H. GREEN.

Inevitably, because of our proximity, it is harder to identify canonical works of twentieth-century liberalism. There was a long period in the twentieth century in which liberal philosophers seemed to lose their taste (or their nerve) for grand theory on the scale of Hobbes or Kant, a period during which they seemed to pride themselves on the piecemeal, analytic and unsystematic character of their thought. In a Cold War context, these were regarded as healthy signs of being 'non-ideological'. That phase seems to have passed, and more confident versions of philosophical liberalism have re-emerged in the work of late-twentieth-century writers like F.A. von Hayek, Robert NOZICK, Ronald DWORKIN, Joseph Raz and, most importantly, John RAWLS (§4).

Some will quibble about one or two of the names on this list. Was Hobbes really a liberal? Was Rousseau? We should remember, however, that 'liberalism' has never been a label over which any group has exercised collective control. As a result, the term is at the mercy of its most casual users, and indeed the attempt to define 'liberalism' is undertaken most commonly not by its practitioners but by its opponents, with predictable caricatural results.

Even so, the challenge is not just to correct misrepresentations. The philosophical positions that we most plausibly identify as liberal often represent distinctive expressions of ambivalence about human nature and political life, rather than dogmatic formulae in a liberal catechism. We have seen this already in the values and principles which constitute liberalism in the political sense: liberals disagree about property, economic equality and the role of the state. At the more philosophical level, liberals disagree about the nature of value, the meaning of freedom and the connection between individual and social purposes.

What follows is an attempt to lay out some of those positions and controversies. But defining liberalism is, on the whole, a frustrating pastime. There are many ways of mapping this philosophical

landscape, and there is no substitute for grappling with the disparate detail of the theories propounded by particular liberal philosophers.

3 Individualism

Let us begin with some basic ethical premises. The deepest commitment of liberal political philosophy is to *individualism*, as a fundamental proposition about value. Liberal individualism has four parts to it.

First, liberals believe that the individual person is what matters for the purposes of social and political evaluation. We may be interested in the fate of a culture, a language, a community or a nation, but for a liberal such interest is always secondary or derivative. Ultimate value has to do with how things are for ordinary men and women, considered one by one: their pains and pleasures, their preferences and aspirations, their survival, development and flourishing. Of course, people do care about each other: individualism is not the same as egoism. But individualism excludes social and collective entities from the realm of ultimate goods.

There is less agreement about the grounds for this individualization of value. John Locke, writing in the seventeenth century, based it on each person being the workmanship and property of God, which meant that we were 'made to last during His, not one anothers Pleasure' (1690). This relation to God was direct, unmediated and unconditional in the case of each individual. It therefore established a basis for our rights with respect to one another that did not presuppose validation by larger social structures.

Modern liberalism, however, is a secular tradition, and its history since Locke's time is largely a history of the attempt to establish this individualism without appealing to the idea of God. Utilitarian thinkers linked the notion of value analytically to desire or preference, and they inferred, from the fact that desiring and preferring were attributes of individuals, that the fundamentals of value must be individualistic too (see UTILITARIANISM). Those following in the tradition of Kant, on the other hand, linked value analytically to the lonely individualism of will, conscience and the sense of duty, and drew the conclusion that each person, *qua* moral agent, was entitled to be regarded as an end in themselves, not just a means to broader social ends. The Kantian view has perhaps fared better in modern political philosophy, although its underlying argument – that because moral thinking takes place at the level of individual minds and wills, individual minds and wills must also be the fundamental objects of moral concern – has yet to be rendered in a compelling form.

Second, liberals believe that there is something particularly important in the capacity of individuals to direct their actions and live their lives, each on their own terms. They believe in the importance of freedom – although what that belief amounts to is one of the controversies referred to earlier. Some define freedom in negative terms: their libertarianism amounts simply to a condemnation of force, coercion and interference in human life. Freedom, they say, is what flourishes when these constraints are taken away, and there is nothing apart from the removal of constraints that needs to be done politically in order for freedom to flourish. Positive conceptions of liberty allow the state a much greater role than this: they may see freedom or autonomy as something to be achieved, rather than taken for granted, in the life of an unrestrained individual, something that requires educated individual capacities and favourable social conditions (see FREEDOM AND LIBERTY).

Some conceptions of positive liberty go well beyond this, moving out of the liberal realm altogether. If freedom is identified with the performance of social duty, or attributed to individuals only by virtue of their participation in some social whole, then the resulting theory can hardly be described as liberal.

Also, if freedom is presented as the achievement of a happy few, something of which the ordinary mass of humanity is incapable, then again we are not dealing with a liberal conception. Although liberal freedom is sometimes a developmental concept, it is not an aristocratic or utopian one. The free direction of a human life is seen as something which ordinary people are capable of, under decent social and political circumstances. When Colonel Rainsborough exclaimed in the Putney Debates of 1647, 'Really, I think that the poorest he that is in England has a life to live as the greatest he', he gave voice to an egalitarianism that lies at the foundations of the liberal tradition.

The third aspect of liberal individualism, then, is a commitment to equality. We have to be careful how we formulate this. Liberal philosophers are not necessarily egalitarians in the economic sense. But they are committed as a matter of the basic logic of their position to a principle of underlying equality of basic worth. People are entitled to equal concern for their interests in the design and operation of their society's institutions; and they have the right to be equally respected in their desire to lead their lives on their own terms (see EQUALITY).

Feminists have sometimes questioned whether this liberal commitment to equality extends across boundaries of gender. In the writings of Locke, Rousseau and Kant it is easy to find throwaway lines that would be described today as sexist or misogynistic. No writer in the liberal canon committed himself explicitly and at length to the

emancipation of women much before J.S. Mill's essay *The Subjection of Women* in 1868. Nevertheless, the legacy of liberal carelessness on this issue does not pose any major theoretical difficulties for the position that men and women are equal in their moral and political capacities and in the respect to be accorded those capacities. Indeed, the more challenging feminist critique is that liberals exaggerate (rather than deny) the similarities between men and women – that they fail to either acknowledge or accommodate crucial elements of 'difference' in moral reasoning and ethical demeanour (see FEMINIST POLITICAL PHILOSOPHY).

A fourth element of liberal individualism involves an insistence on the rights of individual reason. This involves not just freedom of thought, conscience or discussion, but a deeper demand about justification in politics: the demand that rules and institutions of social life must be justified at the tribunal of each individual's reason.

We see here an important connection between liberal thought and the philosophical legacy of the Enlightenment. The Enlightenment was characterized by a burgeoning confidence in the human ability to make sense of the world, to grasp its regularities and fundamental principles and to manipulate its powers for the benefit of mankind. That drive to understand nature is matched in Enlightenment thought by an optimism at least as strong about the possibility of understanding society and human nature. In one aspect, this optimism is the basis of modern sociology, history and economics. But it is also the source of certain normative attitudes towards social and political justification – an impatience with tradition, mystery, awe and superstition as the basis of order, and a determination to make authority answer at the tribunal of reason and convince us that it is entitled to respect. The social world, even more than the natural world, must be thought of as a world *for us* (for *each* of us) – a world whose workings are to be understood by the active enquiries of the individual mind, not by religious dogma, mindless tradition or the hysterics of communal solidarity.

4 The economic side of human nature

Liberals accord intrinsic value to people as individuals, and attach particular importance to each individual's capacity to organize a life on their own terms. What terms are these likely to be? What nature of beings are these whose individual freedom we value? And what are the uses to which their freedom is likely to be put?

Critics commonly associate liberal individualism with an egoistic and acquisitive view of human nature. They say the classic liberals all gave pride of place, among human motivations, to the desire for power, pleasure and material possessions. Humanity, they argue, is reduced in liberal theory to nothing more than a competitive mass of market individuals – voracious consumers with unlimited appetites, hostile or indifferent to the wellbeing of others, and requiring no more of their political and legal institutions than that they secure the conditions for market activity.

The picture is not entirely a distortion. Liberal individualism does recognize that individuals' interests do not necessarily or naturally harmonize with one another. Each individual has a life of their own to lead, and there is no guarantee that one person's desires will not conflict with another's. Sometimes, as in Hobbes' theory, this is represented as an inherent hostility, a competitive diffidence and a 'mutuall will of hurting', issuing in a 'war of all against all'. Sometimes, as in John Rawls' work, it is seen simply as a postulate of mutual disinterest (rather than hostility). Mostly it is seen in Immanuel Kant's words as a matter of the 'unsociable sociability of men' – that there are things we share in common, things that drive us to society, things we can only accomplish together, as well as aspects of our nature that make us prickly, adversarial and wilfully isolated individuals.

Moreover, although – as we shall see – liberals believe that there are terms on which individuals with diverse or even opposed interests can live in peace with one another, it has never been part of their political philosophy that reason, enlightenment or socialization would put an end to this basic diversity or competitiveness. (To the extent that Rousseau suggests that the social contract might produce 'a remarkable change in man', his speculations take him outside the liberal tradition.) In the nature of things, humans will inevitably come up with diverse and opposed views of what makes life worth living, while the exigencies of our situation in the world – the moderate scarcity of material resources and our vulnerability to one another – will always furnish the raw materials for anxiety, competition and conflict (see HUMAN NATURE).

A related objection is that liberals subordinate politics to economics: they see political structures merely as instruments for securing economic peace and market interaction, and they ignore the higher calling for the state outlined, for example, in the theories of Aristotle, Hegel or Hannah Arendt.

The image is accurate, but it is not clear why it should be regarded as an objection. Certainly, liberals do not regard participation in politics as an end in itself; unlike the civic humanists, they do not think that the most important virtues and activities are those oriented towards politics and the formal exercise of power over others (see REPUBLICANISM).

It does not follow that they think of political participation as a narrow self-interested enterprise. In political science, the term 'liberalism' is commonly associated with interest group politics, but philosophical liberals are about equally divided on the question of whether voters in a democracy should orient their decisions to the common good or to their own interests (with the common good emerging as some sort of resultant from the political process). The point, however, is that even those who believe we should vote on our views about the common good still maintain that politics is, in the end, a means to promote the interests of individuals (*all* individuals), not an end in itself. They may believe in Rousseauian democracy, they may even hope that democratic participation can bring out the best in people (although many are dubious about that), but their firmest conviction is that individuals have interests and purposes of their own to pursue which have nothing intrinsically to do with politics or the state, and that the function of government is to facilitate those individual purposes not judge them or replace them with political or social ones.

To say that these purposes are individual is not necessarily to say that they are economic or materialistic in their content. It is surprising, in fact, how few liberal theorists have actually held the economically acquisitive picture of human nature. Hobbes did, certainly, and so did some of the eighteenth-century political economists. But many others in the liberal tradition see material motives as means to individual ends that may well be ethical, even spiritual in their content. John Locke, notorious in some circles as the apostle of possessive individualism, insisted that our primary mission in life is to ascertain what our creator requires of us in the way of conduct and worship: 'the observance of these things is the highest obligation that lies upon mankind, and . . . our utmost care, application and diligence, ought to be exercised in the search and performance of them because there is nothing in this world that is of any consideration in comparison with eternity' (*An Essay concerning Human Understanding* 1689). Modern liberals, too, tend to stress the ethical and cultural character of individual pursuits. We each have our own conception of happiness or the good life – a view about what makes a life worth living – and it is the diversity of individual ideals of this kind that political structures must accommodate.

In general, there is an intriguing ambivalence in the liberal tradition about whether this shift from economic to ethical individualism presents the social problem as more or less intractable. On the one hand, it seems to make the situation look better. Economic conflict is a zero-sum game: what you have I cannot have, or, worse still, what you have puts you in a better position to take what I have away from me; I therefore have an excellent reason of self-protection to deprive you of as many resources as I can. Ethical and spiritual individualism, by contrast, seems less intrinsically competitive: 'one man does not violate the right of another', wrote Locke, 'by his erroneous opinions . . . nor is his perdition any prejudice to another man's affairs' (*Essay* 1689). The appropriate social posture for religious or ethical individualists seems to be the mutual indifference of Rawls' theory rather than the competition or conflict of Hobbes.

In fact, of course, that has not been our experience. Wars of religion have been at least as deadly as wars for territory or resources. We may think of commercial life as bland or shallow, but there is a certain sense of relief in Voltaire's comment about the London Stock Exchange: 'Here Jew, Mohammedan and Christian deal with each other as though they were all of the same faith, and only apply the word infidel to people who go bankrupt'. Even Hobbes, whose *Leviathan* is the *locus classicus* for the economic war of all against all, was adamant that the problem of the struggle for resources could be solved, since people would be willing to make concessions to a strong state that could keep the peace. But sectarian religious fervour he thought of as a form of madness, and he doubted whether the partisans of rival religious ideals could ever come to terms with one another (see TOLERATION).

Critics of liberalism will no doubt persevere in their charge that the tradition flatters the materialistic side of human nature at the expense of cultural and spiritual aspirations. They will say that liberals have paid too much attention to the ways in which political and legal structures can foster market economies and too little to the contribution they can make to the quality of ethical choice. A number of liberal writers have taken this criticism seriously. Joseph Raz, for example, has argued that there is an aspiration towards value in the very concept of autonomy, so that a liberal commitment to freedom should not be thought of as incompatible with a social commitment to ethical perfectionism.

There comes a point, however, when liberal philosophers simply have to stand up and defend the channelling of political energies towards the real (but apparently soluble) problems of famine, plague and poverty, and away from moral, cultural and religious disputes, which promise little more in the way of progress than war, sectarianism and cults of ethical correctness. The preoccupation with economics is not based on scepticism about the ethical or spiritual dimensions of human life. It is based

rather on a moderate sense of what politics can and cannot accomplish in a world where people disagree about God, value and the meaning of life, but largely converge in their desire to avoid hunger and disease and to better their material conditions.

5 The social contract

To the extent that liberal philosophy emphasizes diversity and conflict among individual purposes, it seems to steer us in the direction of anarchism. For what set of actually existing or realistically practicable institutions could possibly accommodate the individualism we have outlined?

In fact, liberal theorists have always held that something like the modern state, with its familiar institutions of law and representative government, *can* be made legitimate. They reject both the anarchist view that freedom is vindicated only in the absence of state authority and obligation and the utopian premise that a just society presupposes a radical change in human nature. This puts them in a rather ambivalent position in so far as existing 'liberal' societies are concerned – meaning here the constitutional democracies of North America, western Europe, Australasia and Japan. Liberalism has been a remarkably successful political ideology, inasmuch as its leading principles – freedom, toleration and equality before the law – have been accepted as part of the self-image or public relations of the world's most powerful and prosperous societies. Its proponents are uneasy, however, with the common inference that the social, economic and political reality of these societies is what liberal principles amount to in practice (just as Marxists were uneasy about the presentation of the Soviet Union and its satellites as 'actually existing socialism'). They insist, quite properly, that liberalism is a set of critical principles, not an ideology or rationalization, and that it provides a basis for condemning things like deepening poverty, secretive and oligarchical government, legal abuses and the continuing legacy of racism and sexism in modern democracies. Even so, the existence of the self-styled 'liberal' democracies is important. It helps sustain the sense that liberalism is a reformist rather than a revolutionary creed and that we already know, at least in outline, what a truly liberal society would be like. That sense of moderate reformism is not just a strategic ideological advantage. Liberalism claims to respect men and women as they are. It does not require generation after generation to undergo sacrifice for the sake of an endlessly postponed utopia. It suggests instead that political structures can be set up in now a way which represents a safe and reasonable compromise among individuals' disparate demands.

In its classical form – in the writings of Hobbes, Locke, Rousseau, and to a lesser extent Kant – the argument from liberal premises to the legitimacy of something like the modern state was presented in terms of the social contract (see Contractarianism). The argument goes something like this.

Imagine people living outside any framework of political authority, exercising the right to direct their own lives and their own dealings with one another, in what liberal philosophers have called 'the state of nature'. Using this as a baseline, try to model the development of political institutions as a way in which individuals exercise their freedom not as a way in which their freedom is abrogated.

The social contract model represents the functions of government in terms of a set of difficulties that such people would face in a state of nature. Conceptions of these difficulties vary. There may be an internecine struggle for resources (Hobbes and Hume); there may be an appreciation of others' rights, but no reliable mechanism for enforcing them (Locke); or there may be disagreement about justice, with each person seeking to do what seems right or good in their opinion (Kant). The common element is that people in the state of nature would lack a reliable sense of what they could count on in social and economic life. What they most need is a secure set of rules, impartially administered and enforced, to provide a framework in which peaceful cooperation and long-term production is possible.

Government, then, is represented in terms of an agreement by each person with all of the others (in a given territory) to cooperate in the institution and maintenance of permanent rule-making and rule-enforcing agencies. The contract is not an agreement between the government and the individual. Instead, it presents legal and governmental institutions as structures of cooperation among individuals, and it uses that idea as a basis for deriving limits on governmental powers and restraints on particular individuals' or factions' exploitation of those powers. Tyrannical exploitation and arbitrary government are ruled out on this conception, inasmuch as they cannot be represented as any sort of improvement over the situation individuals would face if they tried to live without any political institutions at all.

Some theorists, Rousseau and Rawls for example, use the social contract idea also as a way of thinking about the content of legal rules: we can discuss what rights we have and the just distribution of resources by asking what assurances would have to be given to each individual to secure their consent to the basic structure of social arrangements. In the hands of these theorists, the social contract is a test of substantive political justification. Others see it in more procedural terms: the social

contract models the construction of political and constitutional mechanisms, which will then work out substantive solutions on a basis that is relatively independent of the contract idea. Hobbes' theory is the most extreme example of this: the Hobbesian contract is simply an agreement to authorize an individual or organization (a 'sovereign') to solve the problems that generate conflict in the state of nature in any way that promises improvement. The absolute authority with which the sovereign is thus endowed has led some to deny that Hobbes is a liberal. Certainly, he is not wedded to the positions identified with liberalism at the beginning of this article. But his underlying political philosophy is liberal: his value premises are individualistic, and he is unyielding in his view that political institutions (with the powers he accords them) must be justified in relation to the interests of each individual, as well as in his optimism that such justification is possible.

Not all liberal philosophers appeal to the idea of the social contract. Many prefer to develop their theories without the mediation of this model. The arguments of J.S. Mill's 1859 essay *On Liberty*, for example – which many regard as the quintessential statement of liberal principles – are presented directly as claims that individuals are entitled to make, against their society and their government, without any historical pretence that governments were set up by individuals to validate those claims. Others use the social contract to justify some but not all of the political constraints they propose. In the theories of John Locke and Robert Nozick, the social contract argument presupposes a distribution of 'natural' property rights. For them, the function of the social contract is to support and police these rights, not reconceive or redistribute them. In other words, Locke and Nozick propose that property rights should be justified directly in moral argument, without appealing to the social contract idea. I suspect that something like this is true of all liberal theories. The social contract is an intermediate rather than a fundamental idea: one that presupposes that individuals are free, equal and rational, and that political power requires a justification which connects with the interests of each of them.

When it is understood in this way, as a method of modelling the force of certain deeper assumptions or theorems about justification, the social contract can be used as a purely hypothetical device in normative argument. As Kant and Rawls have pointed out, we need not be embarrassed by the fact that no such contract ever took place. It is still a useful test to apply to a constitution or to a set of laws. For if we conclude, even hypothetically, that our laws or our constitution would not have commanded the agreement of all those who are constrained by them, we will have discovered a significant dissonance between our political arrangements and the fundamental (pre-contract) notion of respect for each individual – a dissonance that ought to be of concern to liberal philosophers whether they are interested in the niceties of contract theory or not.

LIBERATION PHILOSOPHY

Philosophy of liberation emerged in Argentina early in the 1970s with the explicit intention of proposing a liberating alternative to the diagnosis of structural dependence offered by the social sciences (particularly the so-called 'theory of dependence'). Some of the original intentions of liberation philosophy were to make poor and marginalized people the subjects, or authors, of philosophy and to collaborate in the process of distancing philosophy from academia and exclusively professional settings. Social conflict and pressing national needs were topics of debate at that time. All thought started with the recognition and assessment of the experience of alterity. Horacio Cerutti-Guldberg has proposed the phrase 'philosophies for liberation' as this kind of reflection deals with multiple philosophical positions and privileges the historical process over philosophy.

LIBERTARIANISM

In political philosophy 'libertarianism' is a name given to a range of views which take as their central value liberty or freedom. Although occasionally the term is applied to versions of anti-authoritarian Marxist theory (the 'libertarian left'), more commonly it is associated with a view which champions particularly pure forms of capitalism. Libertarians endorse the free market and unfettered free exchange, and oppose paternalistic or moralistic legislation (for example, laws regulating sexual behaviour or the consumption of alcohol or drugs). Liberty, on such a view, is identified with the absence of interference by the state or by others. The legitimate state exists purely to guard individual

rights, protecting people and their property from force, theft and fraud. This is the 'minimal state' or 'night-watchman state' of classical liberalism. The state has no authority to engage in the redistribution of property (except to rectify the effects of theft, and so on) or, in certain versions at least, to pursue policies designed to further the common good. Such activities are viewed by the libertarian as illegitimate interferences with an individual's right to do what they wish with their own person or property.

LIFE AND DEATH

Introduction

Problems concerning life and death are among the most dramatic and intractable in philosophy and they feature in all fundamental areas of philosophical inquiry, especially ethics. Most basic is the problem of what account to give of the value of life itself. This problem has had two main dimensions. One has been the controversy over what precise account to give of death; this has revolved around the issue of whether death is, as it is commonly perceived, an evil, and premature death a tragedy. The other has been the equally puzzling question of how to explain the positive value of life, and to resolve the problem that the more rich we make our account of the value of life, the more the value of life, and hence the nature of the wrong done by killing someone, seems to vary with the quality of the life of the person concerned.

A second set of problems concerns the definition of death and appropriate criteria for death. Death, as the most extreme consequence of violence, also leads one into psychological discussions of aggression and into issues of political violence, terrorism, war and capital punishment in political philosophy. Third, there has been concern with a number of practical moral issues, including abortion and euthanasia. Finally, issues have arisen concerning the relation of the value of the life of persons to other sorts of lives, those of animals, for example, or the life and survival of the ecosystem itself.

1 The value of life

It is not only the evil of death that presupposes that life has value and directs us to account for this value, but also everyday discriminations between lives of different sorts. Even the food of vegetarians involves the premature death of living things, and vegetarians usually accept priorities between different animals and between human individuals at different stages of development. If the hospital is on fire, should we attempt to rescue the patients before the hospital cat, and some patients before others? Should the terminally ill, the very old or those in persistent vegetative state be rescued before or after those with radically different life expectancy and degrees of richness and variety in their lives? Should those responsible for their own poor health (heavy smokers, for example) be preferred to the more prudent? Only an account of the value of life will tell us both why lives should be saved and whether and to what extent it is legitimate to choose between lives.

The chief recent attempts to provide a theory of the value of life have sought to identify those features of the most valuable creatures (humans) which might explain their peculiar value. Most theories combine autonomy, self-consciousness and intelligence as the relevant features (see Autonomy, ethical). Creatures with such capacities have often been termed 'persons' (see Persons). Radically different accounts of how to apply such criteria of personhood have emerged. Philosophers of broadly consequentialist orientation have claimed that only creatures who actually possess the relevant characteristics count as persons (see Consequentialism). A major difficulty for such accounts is their counter-intuitive conclusion that creatures which most people do regard as valuable (foetuses and neonates, for example) either are valuable not in virtue of any intrinsic properties that they possess, but only in so far as they are valued by persons properly so called (their parents, perhaps), or will be valuable only in terms of future expected utility.

Others, accepting broadly the same criteria for personhood, have argued that creatures structured to possess such capacities or members of a natural kind that typically possesses such capacities are valuable whether or not particular individuals (foetuses, for instance) actually possess them. Another approach rests content with stipulating that humans are more valuable than others simply in virtue of their species membership. These 'natural kind' theorists cannot account for the discriminations people make between the moral importance of, say, foetuses, and other members of the same natural kind. If the life of a mother and her foetus are in danger and both cannot be saved, most would believe it right to prefer the mother.

Philosophers faced with the sorts of problems considered so far often produce *ad hoc*, 'common-sense' modifications to their general theories to overcome difficulties with hard cases. For example, natural kind theorists often admit of grades of natural kind membership, using terms like 'fully-fledged' humans to account for differences in attitudes to foetuses and adults.

Ronald DWORKIN, in an original account of the value of life, has argued that the sanctity of life must be understood in terms of the waste of investment in life represented by death. Dworkin distinguishes two dimensions of investment that might be wasted by death: the natural and the human. Natural investment implies that nature itself makes an investment in terms of time, trouble and natural resources when life is created and that investment increases in a linear way as the life continues. In the case of human investment, there is both the investment of the human whose life it is (in terms of self-creation both conscious and unconscious) and that of the other people who invest time, effort and resources in creating and sustaining that life. On this view the wrong of causing premature death is that of squandering this natural and human investment. A conservative view of the wrong of euthanasia and abortion, for example, prioritizes natural investment, while a more liberal view will prioritize a particular interpretation of the human contribution to a life.

This and other accounts suggesting that a life is valuable in proportion to its *richness* give importance to factors which differ across lives. On these views, lives will be more valuable the more the investment in them or the more rich and varied they are. This gives rise to the major problem that no two lives will be equally valuable and huge problems of discrimination between people are inevitable.

2 Criteria for death

Since Epicurus there has been persistent philosophical interest in the problem of accounting for the evil of death. We have already presupposed that this problem can be solved by discussing the value of life. Epicurus' problem is in a sense paradoxical. He made substantially the same point as Wittgenstein: 'death is not an event in life'. If it is not, then there is no one to whom death happens, no one for whom death is an evil. But, of course, most people fear death for the disaster it represents. Epicurus' point turns on the necessity of a harm's being experienced, yet we are all familiar with things we rationally regard as harms whether or not we experience them. I have a rational preference not to fall into a persistent vegetative state even if I will not be aware of this happening and thereafter will never be aware of anything again.

The more interesting and important problems concern the nature of the evil death represents and the importance of defining death, or rather of identifying appropriate criteria for the occurrence of death.

If, as most believe, death is an evil, and premature death a tragedy, and if we can say what makes this so, we will also be answering our first question, about what it is that makes life valuable. Here it is important to distinguish the question, 'What makes life valuable – for you?' from the question, 'In virtue of what is life the sort of thing that can be valuable?' The first question is likely to have as many answers as there are persons to whom it is put, the second question rather fewer.

If we move to the issue of criteria for death we can perhaps see why this is so. Death is as old as life, and people have seldom been at a loss as to when grief is appropriate. In other words, death is not a concept which required elucidation. Traditionally, permanent cessation of breath and/or heartbeat was accepted as a reliable indicator of death. While there may have been some uncertainty as to when cessation could be regarded as permanent, the onset of *rigor mortis* and the decomposition of the body could be relied upon to settle the matter in due course.

Problems arose when technology enabled the heartbeat and breathing of individuals to be maintained almost indefinitely. This was so even when the individuals concerned were otherwise so badly injured as to make it certain both that they would never regain consciousness, and that they would die if mechanical support were withdrawn. But are such individuals *dead*? Why is the question important? Why does it even arise?

Individuals on what is popularly known as 'life support' do not appear dead. They breathe, they are supple and perfused with blood, not cold and stiff like a corpse. In order to justify the cessation of life support (I continue with the popular term because it highlights the paradox we are discussing) with the inevitable consequence that the individual would die, it first had to be clear why it was appropriate to let this individual die; why their life had ceased to be valuable, in the sense of worth saving. Second, the technology of efficient life support narrowly preceded the development of organ transplants. If the individual on life support was to be eligible as an organ donor, their organs had to be in good condition. The condition of the organs was optimized by the maintenance of life support. Finally, pressure created by scarce resources meant that the intensive care beds necessary for life support were in demand and their occupation by one individual rather than another had to be justified.

The practical way out of the problem was to invent a new set of criteria for the occurrence of

death. The idea was not to take individuals off life support and wait for them to die, but to declare them dead while still having their life systems sustained. This could be done if death of the brain were to be accepted as a necessary and sufficient condition for death of the organism as a whole. It is now generally accepted in many different societies and cultures that brain death is the criterion for death of the organism as a whole even though the rest of the organism can be kept 'alive' (breathing, blood circulating) after brain death. The major dispute has been over whether whole brain death is necessary for death to be declared to have occurred, or death of the brain stem, the conduit through which all electrical activity in the brain has to pass.

This agreement about brain death is significant, for it surely contains an acknowledgement that it is mental activity, and the things that mental activity supports, that are relevant to the value of life – that when the capacity for consciousness has departed permanently, all that matters has gone. The point of declaring individuals 'dead' was to mark the fact that all that matters about an individual had disappeared and that other things of importance could now be permitted. For example, organs could be made available for donation, intensive care beds released for other urgent cases, friends and relatives released from the often considerable burden of care and support, and grief could begin.

The acceptance of brain death marks a change in understanding of what matters about life and at the same time a reassertion of a traditional conception of respect for the sanctity of life and a correlated insistence that only death takes individuals beyond our moral concern. Brain death is such an attractive notion precisely because it permits the preservation of the concept of death as the crucial moral divide and at the same time allows us to think differently of human individuals who yet breathe. However, the artificiality of brain death as a criterion for the death of the entire organism should be borne in mind. There is an important sense in which brain death is at best a new conception of what it is to be dead and at worst an uneasy compromise between facing squarely the issue of what matters about life and harnessing the massive unreflective consensus about the significance of 'death'.

3 Persistent vegetative state

That this is so can be seen more clearly if we consider the condition of persistent vegetative state, and the landmark judgment by Britain's House of Lords in the case of Tony Bland. Bland sustained brain damage after being crushed in a crowd of spectators at a football match in 1989, at Hillsborough football stadium in Sheffield, England. The brain damage left him permanently and irrevocably unconscious, in what is now termed a 'persistent vegetative state' (PVS). PVS is not fatal; people like Bland can remain alive for thirty or more years. They are not 'brain dead'. In this they are akin to infants born with anencephaly (absence of a brain) or with their cerebral cortex destroyed.

Bland's parents, who accepted that their son had ceased to exist in any real – biographical – sense, although his body remained alive, were prevented from obtaining the solace of grief. In desperation, they asked the English courts to declare that it would be lawful for medical staff to withdraw feeding and other life-sustaining measures so that their son would die. It is not clear why there was any necessity to take the Bland case to the courts, since it was already well established that there was no obligation to sustain a baby by feeding (*Re C* [1989] 2 All ER 782 and *Re J* [1990] 3 All ER 930).

Eventually the House of Lords ruled unanimously that such a course of action would be lawful (*Airedale NHS Trust* v. *Bland* [1993] 1 All ER 821 H.L.). The problem was, of course, that although Tony Bland had permanently ceased to have 'a life' in any meaningful sense, he was not dead and would not die unless the courts permitted doctors to take steps to that end.

A slightly later case was concluded in the Court of Appeal in January 1994. The Master of the Rolls, Sir Thomas Bingham, held, in a bizarre judgment with which the other two lord justices of appeal concurred, that it was permissible for doctors to end the life of a patient by refusing life-prolonging treatment when the consultant and 'a number of other doctors' agreed that such a course was in the patient's best interests and 'no medical opinion contradicted it' (*Frenchay Healthcare NHS Trust* v. *S*, Court of Appeal, Judgment, 14 January 1994). Tony Bland's condition resembled those with brain death in that he had irrevocably lost the capacity for consciousness. The difference is that those in PVS still have electrical activity in the brain and through the brain stem. Does this difference amount to a morally relevant difference between those in PVS and those who are brain dead? Although the House of Lords was reluctant to change the definition of death, or even address that issue, it is clear from its decision that it thought Bland's life, because he had lost all capacity for consciousness, did not retain the sort of value that required it to be sustained. In the words of Lord Keith of Kinkel in his judgment in that case, 'It is, however, perhaps permissible to say that to an individual with no cognitive capacity whatever, and no prospect of ever recovering any such capacity in this world, it must be a matter of complete indifference whether he lives or dies'.

There was no question in Bland's case of competing claims on the resources required to sustain him, so that the decision to permit a course of action designed to achieve the death his parents sought was a deliberate, conscious decision to end his life. A hotly debated question is whether such a decision constitutes a form of euthanasia. Although the House of Lords strongly denied that this is what it was doing, its decision in the Bland case was thought by many to legalize, for the first time in the United Kingdom, a form (albeit very restricted) of euthanasia. That the case of Tony Bland establishes a precedent for legally sanctioned euthanasia in the United Kingdom is confirmed by the words of Lord Mustill in his judgment in that case:

> The conclusion ... depends crucially on a distinction drawn by the criminal Law between acts and omissions, and carries with it inescapably a distinction between, on the one hand what is often called 'mercy killing', where active steps are taken in a medical context to terminate the life of a suffering patient, and a situation such as the present where the proposed conduct has the aim for equally humane reasons of terminating the life of Anthony Bland by withholding from him the basic necessities of life. The acute unease which I feel about adopting this way through the legal and ethical maze is I believe due in an important part to the sensation that however much the terminologies may differ the ethical status of the two courses of action is for all relevant purposes indistinguishable.

The key features of Lord Mustill's judgment are, first, the acknowledgement that the course of action requested of, and approved by, the courts 'has the aim . . . of terminating the life of Anthony Bland'; and, second, that the supposed difference between acts and omissions relied on by the common law tradition to make moral and legal distinctions, characterizes two courses of action that are ethically 'for all relevant purposes indistinguishable'. This decision made the United Kingdom the second country in Europe to have judicially recognized the necessity of bringing to an end the lives of at least some innocent individuals who have not requested death. The Netherlands legalized euthanasia under certain conditions in a High Court case decided in 1984 and later formally enshrined euthanasia in its legal system.

It is important to emphasize the proviso 'who have not requested death', for other instances of courts defending the right to die have turned on precisely this issue. The landmark United States case concerning PVS, that of Nancy Cruzan, depended crucially on whether Cruzan had expressed a wish to die prior to falling into PVS, and indeed it is often described as a case establishing the right to die (*Cruzan* v. *Director, Missouri Department of Health* [1990] 497 US 261).

4 *The ethics of euthanasia*

Arguments about the ethics of euthanasia are essentially the same as, and have been coloured by, arguments about the ethics of suicide. The wrong of suicide has, since the death of Socrates, often been seen in terms of either a violation of some idea of the sanctity of life, or the wrong of depriving a sovereign or a god of the use of a body which was theirs to dispose of. Euthanasia, as essentially assisting suicide, while of contemporary relevance as we have seen, has reawakened the centuries old debate about suicide (see Suicide, ethics of).

Those who defend the legitimacy of euthanasia have three main approaches to defending the ethics of what they propose. First, some see euthanasia (like suicide) as a dimension of human freedom and argue that the value represented by respect for autonomy is incomplete unless it encompasses the limiting case of suicide or assisted suicide. On this view, no further justification is required. The second view is based on compassion and tends to undermine this purist approach to the ethics of euthanasia. It argues that suicide and euthanasia are legitimate ways of bringing to an end suffering which cannot be adequately controlled or ended in any other way. This approach can undermine autonomy because it lapses if there is an equally effective way of controlling the pain and suffering. The third type of defence of euthanasia is exemplified by Ronald Dworkin's account (see §1), which argues that respect for the intrinsic value of life, properly understood, sees life essentially as meaningful and valuable because of the shape given to it by the individual whose life it is, and that this shaping power must include control over life's end. Unlike the first defence of euthanasia which appeals simply to autonomy, Dworkin's approach places autonomy at the service of, and hence subordinate to, a conception of the intrinsic value of life. On this view it is not all autonomous decisions to end life that are justified, but only those which conduce to the agent's own conception of what it is that makes their life make sense.

Arguments against the legitimacy of euthanasia take two forms: they take a stand on principle or they attempt to undermine the cogency of the arguments in favour of euthanasia. The principled approach either harkens back to the idea that an individual's life is not theirs to dispose of, belonging

to the sovereign or the deity or both (one via the other), or takes a stand on the sanctity of life. The more pragmatic approach tends to suggest that the freedom to end one's own life is not part of autonomy properly understood, or that there are other compassionate and effective ways of controlling pain, both physical and psychological.

It is difficult to resolve the differences over euthanasia when the issue is one of principle. Perhaps the most obvious reconciling strategy is to seek cases in which those opposed to euthanasia would concede the legitimacy of killing, and ask if related justifications might not hold good in the case of euthanasia. For example, not all opponents of euthanasia are pacifists, and even pacifists might understand extreme exceptions to the rule against killing the innocent.

One test might be how people feel about the following case. A lorry driver is trapped in the blazing cab of his vehicle following an accident. A policeman is on the scene and sees that the driver cannot be extracted before the flames get to him and he is burned alive. The policeman can let him be burned alive or can give him a quick and relatively painless end by shooting him in the head. The driver says, 'Please shoot me; do not let me be burned alive!' Those opposed to euthanasia in all circumstances must give one answer to the policeman's dilemma, those in favour will give the alternative.

There is one final sort of objection to euthanasia. It avoids the policeman's dilemma but has its own problems. Some people are not opposed to euthanasia on principle and would permit it in exceptional cases, like the policeman's dilemma. However, they regard it as constituting a 'slippery slope' which if permitted would lead to unacceptable forms of killing. They therefore object to the *legalization* of euthanasia, but can cope with isolated and exceptional instances, by forgiveness rather than by justification. The question advocates of the slippery slope objection must answer is whether it is reasonable and rational to criminalize behaviour they admit to be both moral and defensible, and whether or not the unacceptable levels of the slope can be guarded against in another way.

5 Contraception and infanticide

Contraception raises issues of life and death analogous to those we have discussed. First, there are methods of contraception which operate to effect early abortion by, for example, preventing implantation of a fertilized egg. Second, those who regard the potentiality argument as giving moral status to the foetus will, if they are consistent, see contraception as one way in which potential human beings have their potential frustrated. There is, of course, another dimension to the ethics of contraception which is not related straightforwardly to issues of life and death. That is where one sexual partner conceals from the other the nature, existence and/or reliability of the methods of contraception used or leads the other partner to believe a method of contraception is being used when it is not (see TRUTHFULNESS).

Since the advent of HIV/AIDS, a popular method of contraception has become more significant as a barrier to infection, and this has added to the moral responsibility of using one particular method of contraception. Questions are often raised as to whether someone who uses no method of contraception, or fails to use a condom, is willing to conceive and bear the responsibility of a child or is willing to run the risk of HIV infection.

It is sometimes suggested, particularly by Catholic thinkers, that contraception subverts the purpose of sex, which supposedly was designed by the deity for procreation. This is a curious argument, however, because if sexual relations are wrong except when they could conceivably result in procreation, then sex between infertile people or during pregnancy is wrong. If, on the other hand, it is practices which weaken the prospect of new people coming into existence which are to be avoided, then it looks as though it is a celibate priesthood, or the existence of nunneries, which are an affront to God's purpose.

Infanticide raises special moral problems only for those who see a morally relevant difference between the foetus and the neonate. If abortion is permissible, infanticide will surely be permissible on the same terms, unless the newborn differs in some relevant way from those foetuses the abortion of which is permissible. Attempts have been made to identify such differences in three main ways: in terms of either some capacities possessed by the newborn and not the foetus, or the newborn's supposedly greater potential for personhood, or the social relations it forms for the first time on consciously encountering other beings. All of these alleged differences are controversial, and we should note that the last, socialization, leaves unprotected any and all unloved, unwanted and unclaimed infants (see REPRODUCTION AND ETHICS).

JOHN HARRIS

LIFE, MEANING OF

This is an obscure yet central topic in philosophy. Often associated with the question whether human beings are part of a larger or divine purpose, the question, 'What is the meaning of life?' seems to invite a religious answer. Much philosophical discussion, however, questions the necessity of this association. Attention to the inevitability of death has often seemed to make life's meaning problematic, but it is not obvious how immortality could make the difference between meaning and its absence. The theme of absurdity runs through much discussion of those who believe the universe to be indifferent. Though our lives have no significance, they argue, we must live as if they do. In the face of this absurdity, some advocate suicide, others defiance, others irony. One may also turn away from the issue of cosmic significance, and look for meaning elsewhere.

SUSAN WOLF

LIFE, ORIGIN OF

The appearance of maggots on meat or of intestinal tapeworms supported an ancient belief in the spontaneous generation of life. This idea was challenged in the seventeenth century but not abandoned before Pasteur's experiments. Scientists now agree that terrestrial life had a single origin, but differ in explanations. Some believe that life began with the onset of protein-based metabolism, supported by evidence of spontaneous abiotic amino acid synthesis and theoretical models of self-sustaining and evolving systems of enzymes. Others believe life began with the appearance of nucleic acid-based molecular replicators and have organized their research efforts around the vision of a primordial 'RNA world'.

LENNY MOSS

LIMBO

According to traditional Roman Catholic teaching, limbo is the postmortem destination of those who have not been baptized, but are not guilty of sin. Lack of baptism bars such people from salvation, but their innocence means that they do not deserve the punishment of hell. They were thought to fall into two groups: the righteous of the Old Covenant, prior to the redemption of Christ, and unbaptized children. The former were supposed to have gone to heaven after Christ's death, but the latter had to stay in limbo forever. The existence of limbo was never dogmatically defined, and it was never given as much attention as heaven, hell or even purgatory, each of which represented a fate which human beings earned in part through personal choice. Nowadays, the possibility that unbaptized babies might be consigned to hell is not widely entertained, and some thinkers hold that the requirement of baptism for salvation is open to interpretation. Consequently, the idea of limbo is not as widely discussed as it once was.

LLULL, RAMON (1232–1316)

One of the most extraordinary figures of thirteenth-century Europe, Llull was a self-taught lay theologian and philosopher, chiefly concerned with reforming Christian society and converting unbelievers. Details of his life remain obscure, but over 200

of his writings survive. Most of these expound his personal dialectical system, the Great Universal Art of Finding Truth, an encyclopedic collation of commonplace doctrines that attempts to show how all human knowledge conforms to divine truth. Largely ignored during Llull's lifetime and denounced as heretical in the later Middle Ages, the Great Art became very popular in the Renaissance as a programme of universal knowledge.

LOCKE, JOHN (1632–1704)

Introduction

John Locke was the first of the empiricist opponents of Descartes to achieve comparable authority among his European contemporaries. Together with Newton's physics, the philosophy of *An Essay concerning Human Understanding* gradually eclipsed Cartesianism, decisively redirecting European thought. Neoplatonic innatism was replaced with a modest, naturalistic conception of our cognitive capacities, making careful observation and systematic description the primary task of natural inquiry. Locke saw himself as carrying out just such a descriptive project with respect to the mind itself. Theorizing is the construction of hypotheses on the basis of analogies, not penetration to the essences of things by super-sensory means. In religion Locke took a similarly anti-dogmatic line, advocating toleration and minimal doctrinal requirements, notably in *Epistola de tolerantia* (A Letter concerning Toleration) and *The Reasonableness of Christianity.* Through his association with the Earl of Shaftesbury he became involved in government, and then in revolutionary politics against Charles II and James II. The latter involvement led to exile, and to *Two Treatises of Government*, a rejection of patriarchalism and an argument from first principles for constitutional government in the interests of the governed, and for the right of the misgoverned to rebel. Locke published his main works only after the 'Glorious Revolution' of 1688. He undertook important governmental duties for a time, and continued to write on many topics, including economics and biblical criticism, until his death. The *Essay*, *Epistola* and *Second Treatise* remain centrally canonical texts.

Locke held that all our ideas are either given in experience, or are complex ideas formed from simple ideas so given, but not that all our knowledge is based on experience. He accepted that geometry, for example, is an a priori science, but denied that the ideas which are the objects of geometrical reasoning are innate. 'Experience' includes 'reflection', that is reflexive awareness of our own mental operations, which Cartesians treated as a way of accessing innate ideas, but which Locke calls 'internal sense'. To have ideas before the mind is to be perceiving given or constructed sensory or quasi-sensory images – things as perceived by sense. In abstraction, however, we consider only aspects of what is presented: for example, a geometrical proof may consider only aspects of a drawn figure, allowing generalization to all figures similar in just those respects. Universal knowledge is thus perception of a relation between abstract ideas, but we also have immediate knowledge, in sensation, that particular external things are causing ideas in us. This awareness allows us to use the idea as a sign of its external cause: for example, the sensation of white signifies whatever feature of objects causes that sensation. Representation is thus fundamentally causal: causality bridges the gap between reality and ideas. Consequently we have sensitive knowledge of things only through their powers, knowledge of their existence without knowledge of their essence. Each way in which things act on the senses gives rise to a phenomenally simple idea signifying a quality, or power to affect us, in the object. Some simple ideas, those of the 'primary qualities', solidity, extension, figure, motion or rest, and number (the list can vary) can be supposed to resemble their causes. Others, ideas of 'secondary qualities', colour, smell, taste and so forth, do not. We also form ideas of the powers of objects to interact.

Our idea of any sort of substantial thing is therefore complex, including ideas of all the qualities and powers by which we know and define that 'substance'. Additionally, the idea includes the 'general idea of substance', or possessor of the qualities, a placemarker signifying the unknown underlying cause of their union. Locke distinguishes between the general substance, matter, and the 'particular constitution' of matter from which flow the observable properties by which we define each sort of substance – gold, horse, iron and so on. This 'real constitution' or 'real essence' is distinguishable only relatively to our definition or 'nominal essence' of the species. Locke extends this conceptualist view of classification to individuation in a famous, still influential argument that a person is individuated, not by an immaterial soul, but by unifying and continuous consciousness.

Because their real essences are unknown to us, we are capable only of probable belief about substances, not of 'science'. In mathematics, however, real essences are known, since they are abstract ideas constructible without reference to reality. So too with ideas of 'mixed modes' and 'relations', including the ideas of social actions, roles and relationships which supply the subject-matter of a priori sciences concerned with law, natural, social and positive. The three legislators are God, public opinion and government. God's authority derives from his status as creator, and natural or moral law is his benevolent will for us. Locke's political theory concerns the authority of governments, which he takes to be, at bottom, the right of all individuals to uphold natural law transferred to a central agency for the sake of its power and impartiality. Economic change, he argues, renders this transfer imperative. In a state of nature, individuals own whatever they have worked for, if they can use it and enough is left for others. But with land-enclosure (which benefits everyone by increasing productivity) and the institution of money (which makes it both possible and morally justifiable to enjoy the product of enclosure) this primitive property-right is transcended, and there is need for an authority to ordain and uphold rules of justice for the benefit of all. Any government, therefore, has a specific trust to fulfil, and should be organized so as best to safeguard this role. A ruler who rules in his own interest forfeits all rights, as a criminal at war with his subjects. Then rebellion is justified self-defence.

1 Life and main works

John Locke was born at Wrington, Somerset in England on 28 August 1632. His father was a small property owner, lawyer and minor official, who served on the side of Parliament in the civil war under the more influential Alexander Popham. Through Popham, Locke became a pupil at Westminster School, then the leading school in England. From Westminster he was elected in May 1652 to a Studentship at Christ Church, Oxford, conditionally tenable for life.

During the next fifteen years at Oxford Locke took his degrees (B.A. 1656, M.A. 1658) and fulfilled various college offices, becoming Tutor in 1661. Between 1660 and 1662 he wrote three manuscripts on issues of Church and State, individual conscience and religious authority, two now published together and known as *Two Tracts on Government*, and *An necesse sit dari in Ecclesia infallibilem Sacro Sanctae Scripturae interpretem?* (Is it necessary to have in the church an infallible interpreter of holy scripture?). Although his answer to the last question was predictably negative, in the *Tracts* he expressed a less-than-tolerant view of conscientious religious unorthodoxy, assigning to rulers the right to determine details of religious observance for the sake of public peace. While Censor of Moral Philosophy at Christ Church in 1664 he completed the Latin manuscript now known as *Essays [or Questions] on the Law of Nature*, which presaged his mature views – both his general empiricism and his conception of moral obligation as an obligation to God to obey natural law. This work also rejects wayward and dogmatic appeals to conscience, in favour of reason based on experience.

The politics of religion, at the time a large part of politics, was not Locke's only extracurricular interest. His reading-notes ('commonplace books') of this time indicate an interest in Anglican theology, and by 1658 he was reading and taking lecture notes in medicine with the assiduity appropriate to a chosen career. This interest extended to chemistry and, in the 1660s, to the new mechanical philosophy as expounded, for example, by Robert Boyle, whom Locke had met by 1660. Locke also read the main philosophical works of Descartes, and some Gassendi, but his record focuses on their versions of corpuscularianism, bypassing metaphysical and epistemological underpinnings (see Descartes, R. §§11–12; Gassendi, P.). On the evidence, natural philosophy attracted Locke more at this time than metaphysics, although the coarse empiricism of *Essays on the Law of Nature* is close to that of Gassendi. Yet Locke could hardly have remained ignorant of the battle among the new philosophers between 'gods' and 'giants' – between those, led by Descartes, in the Platonic-Augustinian metaphysical tradition and those, headed by Gassendi and Hobbes, who developed ancient empiricist and materialist theory.

In 1665 Locke's university life was interrupted by a diplomatic mission to Brandenburg as secretary to Sir Walter Vane. About this time he decided against entering the Church, but took the one way of

nevertheless keeping his Studentship (without obligation to reside in Oxford) by transferring formally to medicine. In 1666 came a momentous meeting with Lord Ashley (Anthony Ashley Cooper, who became Earl of Shaftesbury in 1672), whose London household Locke subsequently joined in 1667. Here his medical and political interests alike received a more practical edge than they had previously possessed. He began collaborating closely with the pre-eminent physician, Thomas Sydenham, and in 1668 successfully supervised an operation on Lord Ashley to drain an abscess on the liver. In the years following he continued to act as medical advisor within Ashley's circle, supervising the birth of Ashley's grandson, later the philosophical Third Earl of Shaftesbury. A manuscript of this time in Locke's handwriting (but perhaps wholly or partly by Sydenham), 'De Arte Medica', is strongly sceptical of the value of hypotheses, as opposed to experience, in medicine.

During this same period, presumably influenced by his patron, Locke wrote the manuscript *Essay concerning Toleration* (1667), departing from his earlier, nervously illiberal justification of constraint and advocating toleration of any religious persuasion not constituting a positive moral or political danger – provisos excluding, respectively, atheists and Roman Catholics. In 1667 Ashley became a member of the governing 'cabal' which followed Clarendon's period as Lord Chancellor, and in 1672 became Lord Chancellor himself. Under Ashley, and for a while after Ashley's fall from office in 1673, Locke was involved in government. He began to work on economic questions, and for some years helped in the organization of the newly founded colony of Carolina. He was registrar to the commissioners of excise (perhaps a sinecure) from 1670 to 1675, secretary for presentations (in charge of ecclesiastical patronage) in 1672–3, and secretary and treasurer to the Council for Trade and Plantations (no sinecure) in 1673–4.

Nevertheless he found time for new intellectual interests. Not later than 1671 he put down for discussion by a group of friends what he later claimed (inaccurately, given *Essays on the Law of Nature*) to have been his first thoughts on the powers of the understanding. He found the topic sufficiently gripping for a more extensive treatment than such an occasion would have demanded in *Intellectus humanus cum cognitionis certitudine, et assensus firmitate* (The human intellect, the certainty of knowledge and the confirmation of belief), dated 1671, with a longer (and as strongly empiricist and imagist) redrafting in the same year entitled 'An Essay concerning the Understanding, Knowledge, Opinion and Assent' – the manuscripts now known as Drafts A and B of *An Essay concerning Human Understanding*.

In 1675 Locke moved to France, beginning at the same time to write his journal. He met physicians and philosophers, undertook a programme of reading in French philosophy and continued working on his 'Essay'. On returning to England in 1678, after the fabricated 'Popish plot', he was again caught up in politics and in attempts to exclude Charles' brother James from the succession. Charles dissolved Parliament in 1681, and Shaftesbury led a group of Whigs planning insurrection. During this period Locke probably wrote the bulk of the *Two Treatises of Government*; the first, at least, to support moves for James' exclusion, the second possibly later to advocate actual rebellion. He also wrote, with James Tyrrell, a long response (still unpublished, 1997) to Edward Stillingfleet's *Unreasonableness of Separation*, defending the position of nonconformists against Stillingfleet's criticisms. In 1682 Shaftesbury went into exile, dying soon after. When the Rye House plot to assassinate Charles and James was uncovered in 1683, Locke himself prudently moved to Holland, where he contacted other, more overtly active exiles. His connections provoked expulsion from his Christ Church Studentship in 1684, and at the time of Monmouth's rebellion he went into hiding to escape arrest. His intellectual activities continued unabated, the *Essay* being largely written by 1686. In 1685–6 he wrote *Epistola de Tolerantia* (Letter concerning Toleration), perhaps in response to the revocation of the edict of Nantes. He made friends, and discussed theological questions, with the remonstrant Philippus van Limborch and Jean Le Clerc, publishing various items in the latter's journal, *Bibliothèque universelle et historique*, including a review of Newton's *Principia* (1686) and a ninety-two page abridgement of the *Essay* (1688).

In 1688 the 'Glorious Revolution' brought the deposition of James, and Locke returned to England the following year. He declined the post of ambassador to Brandenburg, accepted an undemanding post as commissioner of appeals (annual salary, £200) and set about publishing his writings. *Epistola de Tolerantia* was published pseudonymously in Holland in May 1689, and Popple's English translation followed within months. The *Two Treatises* were revised and published anonymously, and the *Essay* followed in December (with authorship acknowledged), although both books were dated 1690. *A Second Letter concerning Toleration* (1690) and *A Third Letter for Toleration* (1692) were in response to attacks by an Anglican clergyman, Jonas Proast. *Some Considerations of the Consequences of the Lowering of Interest and Raising the Value of Money*, partly based on the manuscript of 1668, was published in 1691 (dated 1692) against Parliamentary measures of the time. In 1691, Locke accepted the invitation of an old friend, Damaris Masham

and her husband to live with them, as far as his concerns permitted, at Oates in Essex. Country life seems to have ameliorated the asthma which dogged his last years. *Some Thoughts concerning Education* (1693, revised 1695), a significant work in the history of educational theory, was based on a number of letters of advice to his friend, Edward Clarke. In 1694 came the second edition of the *Essay*, with important additions including a controversial chapter on identity. In 1695 he published a new work, once more anonymously, *The Reasonableness of Christianity*. John Edwards' attacks on its liberal, minimalist interpretation of Christian faith were rebutted in two *Vindications* (1695, 1697).

Locke continued to be engaged on economic questions, and in 1695 he joined a committee to advise the Chancellor of the Exchequer on monetary policy. His recommendations, supported by further papers, were accepted. In 1696 came an important government appointment to the Council for Trade and Plantations, and for four years he fulfilled fairly onerous duties on the Board of Trade for the considerable annual salary of £1,000. At the same time he engaged in an extended controversy with Edward Stillingfleet, who found the *Essay* theologically suspect. *A Letter to the Right Reverend Edward, Lord Bishop of Worcester* was followed by two further Letters in reply to Stillingfleet's Answers. Despite its controversial style, Locke's argument is often a cogent clarification of his position. The exchange prompted significant alterations to the fourth edition of the *Essay* (1700) and long passages were included as footnotes in the posthumously published fifth edition. In June 1700 Locke resigned from the Board of Trade, a sick man, and thereafter lived mostly at Oates. Pursuing a long-standing interest in biblical criticism, he set about the work which was posthumously published as *A Paraphrase and Notes on the Epistles of St Paul*, an important contribution to hermeneutics. In 1702 he wrote the reductive *Discourse of Miracles*, and in 1704 began a *Fourth Letter on Toleration*. On 28 October 1704 he died as Damaris Masham read to him from the Book of Psalms. For the last years of his life he was generally respected as, with Newton, one of Britain's two intellectual giants, a reputation undiminished by death.

2 The structure of Locke's empiricism

Locke's mature philosophy is 'concept-empiricist', but not 'knowledge-empiricist': he held that all our concepts are drawn from experience, but not that all our knowledge is based on experience. Yet his early position, in *Essays on the Law of Nature* and the first part of *Draft A*, was 'knowledge-empiricist' in just this sense – even the axioms of geometry gain assent 'only by the testimony and assurance of our senses' (*Draft A* I: 22–3). However, according to *Draft A*, when we find that certain relations hold without exception, we assume that they hold universally and come to employ them as 'standards' of measurement embodied in the meaning of our terms. Locke sees this as implying a choice: an axiom can *either* be interpreted as an 'instructive' but uncertain summary of experience, *or* as a quasi-definition, founded on experience but 'only verbal . . . and not instructive'. But later in *Draft A* he discards the notion that geometrical axioms can be interpreted empirically, taking them only in a sense in which they can be known by 'demonstration' or 'the bare shewing of things or proposing them to our senses or understandings' (*Draft A* I: 50) – that is, by intuitions with perceived or imagined instances (for example, diagrams) as their objects. At the same time he recognizes that mathematical propositions are not plausibly regarded as merely verbal. The possibility of alternative interpretations of universal propositions, *either* as certain, but verbal, *or* as instructive, but uncertain, is now restricted to propositions about substances, such as 'Man is rational'. Locke has shifted, in effect, from knowledge-empiricism towards a concept-empiricism which allows 'instructive' a priori knowledge (the last being the acknowledged ancestor of Kant's synthetic a priori – see KANT, I. §4).

Locke's intuitionism shapes his attack on the innatism characteristic of the Platonic-Augustinian-Cartesian tradition. Starting with propositions, Locke rebuts the argument from alleged universal assent, or assent by all who have come to the use of reason. But ideas are what is before the mind in thought, and propositions are ideas in relation. Locke's underlying thesis is that to take either knowledge or ideas to be innately 'imprinted on the mind' in a merely dispositional sense (and they are clearly not actual in all human beings from birth) would be contrary to any intelligible notion of being 'in the mind': 'Whatever idea was never perceived by the mind, was never in the mind' (*Essay* I.iv.20). Locke concedes dispositional knowledge and ideas, retained by the memory and capable of being revived, but he understands both intentionality and knowledge in terms of perception, and finds nonsensical the notion of perception which never has been conscious and actual. This strongly intuitionist model rules out dispositional innatism as an intelligible possibility. Rationalist intuitionism, from Locke's point of view, is simply incoherent. And since the only dispositional ideas and knowledge are what is retained in the memory, what is before the mind as the object of intuition or demonstration must be experiential or sensory.

Locke also argues that there are no general maxims of logic or mathematics to which all assent

when they come to the use of reason, since many rational but illiterate people never consider such abstract principles. He does not accept that reasoning merely consonant with logical principles is equivalent to assent to them, or, for example, that distinguishing two things is tacit employment of the idea of identity. Explicit abstract principles and ideas come late and with so much difficulty that people cannot agree on ideas of impossibility, identity, duty, substance, God and the like – just the ideas most supposed innately luminous. That rational people assent to certain propositions on first proposal is beside the point, since such people will only have understood the terms of the proposition in question by abstraction from experience. Then they will assent, not because the proposition is innate, but because it is evident. To describe the bare capacity to perceive such truths as the possession of innate principles and ideas will make all universal knowledge innate, however specific or derived. Turning to practical principles and the idea of God, Locke appeals to anthropology to rebut the claim that any of these are universally recognized. The main thrust of his argument, however, is conceptual.

Locke's empiricism has another central feature. Like Gassendi and Hobbes, he expressly accords independent authority to the particular deliverances of the senses. Descartes had argued that sensation requires interpretation employing innate, purely intellectual ideas even in order for us to conceive of its objects as independent bodies. For Descartes, moreover, natural sensory belief is defenceless in the face of sceptical argument – secure knowledge of the existence of bodies can only be achieved through a rational proof involving reflection on the role and mechanisms of sense (see Descartes, R. §9). This emphatic subordination of sense to reason Locke rejects just as firmly: the senses are 'the proper and sole judges' of the existence of bodies. He sees the senses as knowledge-delivering faculties in their own right, prior to any understanding of their mechanisms: 'the actual receiving of ideas from without . . . makes us know, that something doth exist at that time without us, which causes that idea in us, though perhaps we neither know nor consider how it does it' (*Essay* IX.xi.2). The sceptic's doubt about the external world is a mere pretence, not to be taken seriously: 'no body can, in earnest, be so sceptical, as to be uncertain of the existence of those things which he sees and feels'. Echoing Lucretius, Locke sees the reason employed in sceptical argument itself as standing or falling with the senses: 'For we cannot act any thing, but by our faculties; nor talk of knowledge itself, but by the help of those faculties which are fitted to apprehend even what knowledge is' (*Essay* IX.xi.3). Locke does identify features of sense-experience which militate against scepticism: for example, sensory ideas depend on physical sense-organs, and are systematically and unavoidably consequent on our situation; the deliverances of different senses cohere; there is a 'manifest difference' between ideas of sense and ideas of memory and imagination (most dramatically with respect to pain), as there is between acting in the world and imagining ourselves acting; and so on (*Essay* IX.xi.4–8). Yet all these considerations are simply 'concurrent reasons' which further, but unnecessarily confirm 'the assurance we have from our senses themselves' – 'an assurance that *deserves* the name of knowledge' (*Essay* IX.xi.3).

Locke's explanation of the certainty and extent of 'sensitive knowledge of existence' hinges on his view that in sensation we are immediately aware, not only of sensations or 'ideas', but of their being caused by things outside us. We are thus able to think of the unknown cause through its effect in us: 'whilst I write this, I have, by the paper affecting my eyes, that idea produced in my mind, which, whatever object causes, I call *white*; by which I know, that that quality or accident (i.e. whose appearance before my eyes, always causes that idea) doth really exist, and hath a being without me' (*Essay* IX.xi.2). This claim ties in with another, that ideas of simple sensory qualities are always 'true', 'real' and 'adequate': 'their truth consists in nothing else, but in such appearances, as are produced in us, and must be suitable to those powers, [God] has placed in external objects, or else they could not be produced in us' (*Essay* II.xxxii.14). Simple ideas are 'distinguishing marks' which fulfil their function well enough whatever unknown difference lies behind the sensible distinction. But this function fits them for another, as terms in the natural language of thought. The idea of white signifies, that is *indicates*, its unknown cause, and also signifies, that is *stands for*, that feature of things in thought. So the limited causal knowledge that sensation supplies allows us to have contentful thought and knowledge of the external world. The idea of power extends such pretheoretical knowledge: our idea of the melting of wax, joined to the idea of active or passive power, can be employed as a sign of whatever in the sun melts wax, or of whatever in wax causes its melting. Consequently Locke decides to treat ideas of powers as simple ideas, and knowledge of powers as observational. The senses do not give knowledge of the essence or nature of bodies, but they do give knowledge of their existence, and enable us to distinguish between them.

3 Ideas of sensation and reflection: their retention and abstraction

Locke's employment of the word 'idea' responds to a variety of antecedents. Like Descartes, he uses it

ambiguously both for representative states (acts, modifications) of mind and, more frequently, for the represented objects as they are represented or conceived of, the so-called 'immediate' objects of perception and thought. To have an idea before the mind is generally, for Locke, to be contemplating something under a certain conception rather than contemplating a psychological state. To 'perceive a relation between ideas' is to perceive a relation between things-as-conceived-of. But Locke's account also looks back to the Epicurean view of sensations as signs of their unknown causes in the motion of atoms or 'corpuscules' (see §2), a view which points away from the Cartesian and scholastic presumption of intrinsically representative elements in thought towards a purely causal understanding of representation, treating ideas as blank sensory effects in the mind. Locke never resolves the tension between these different conceptions of an idea, although each of them is necessary to his theory.

Locke strongly opposes the Augustinian-Cartesian view that knowledge and truth consist in the conformity of human conceptions with God's conceptions, the divine ideas or archetypes employed in creation and revealed to us in our active use of reason. For Descartes, human reason is only accidentally involved with the senses, whereas for Locke there are no purely intellectual ideas. The task traditionally assigned to intellect – universal thought – Locke assigns to 'abstraction', taken to be the mind's in some sense separating out elements of raw experience and employing them as 'standards and representatives' of a class. What this means will be considered.

Although Locke sometimes writes that all words stand for ideas, ideas are the mental correlates of terms or names: that is, words that can stand in subject or predicate place. He adheres to the traditional view that 'particles', such as prepositions, conjunctions, the copula and the negative, signify, not ideas, but 'the connection that the mind gives to ideas, or propositions, one with another' (*Essay* III.vii.1). They do not *name*, but *express* 'actions of the mind in discoursing': for example, 'but' expresses various mental operations together named 'discretive conjunction'. The mental actions or operations expressed by 'is' and 'is not' are either the 'perception of the agreement or disagreement of ideas', which is Locke's definition of (at least, general) knowledge, or the 'presumption' of such a relation, which is Locke's account of belief or judgment. As commonly in earlier logic, merely considering a proposition is not distinguished from knowing or judging it to be true.

The aim of Book II of the *Essay* is to establish that all our ideas derive from experience: that is, that the way we conceive of the world (including ourselves) is ultimately determined by the way we experience the world. 'Experience' includes not only 'sense', but reflection ('reflexion') – not reflection in today's sense but reflexive awareness of our own mental operations. Platonists, Aristotelians and Cartesians all assigned the reflexive awareness of thinking to intellect rather than to sense. For Descartes, the innateness of such ideas as *substance*, *thought* and even *God* consists in the potentiality of their becoming explicit through the mind's reflecting on itself, and Leibniz argues accordingly that, simply by admitting reflection as well as sense, Locke admits innate ideas (see Leibniz, G.W. §8). Locke, however, claims that reflection, 'though it be not sense, as having nothing to do with external objects, yet it is very like it, and might properly enough be call'd internal sense' (*Essay* II.i.4). Thereafter he treats sense and reflection as theoretically equivalent (although reflexive knowledge of one's own existence is 'intuitive' rather than 'sensitive' – *Essay* IV.ix.3). This move not only extends the empiricist principle to such non-sensory notions as *willing*, *perceiving*, *contemplation* or *hope*, but also contradicts the Cartesian model of thought as transparent to itself, propounding a gap between how thinking appears to the subject and what it really is in itself – the latter being unknown. Locke also insists that reflection is second-order awareness, presupposing sense-perception as the first mental operation. And though 'ideas in the intellect are coeval with sensation' (*Essay* II.i.23), it seems that the mind must 'retain and distinguish' ideas before it can be said to 'have ideas' dispositionally, stored in the memory for employment as signifiers in thought. Ideas of reflection in particular are achieved only 'in time' – and here 'reflection' acquires some of its modern affinity with 'contemplation'. Children, Locke's accounts of both reflection and particles imply, can discern or compound ideas without having the ideas of discerning or compounding, and few of those who employ particles to *express* various mental actions ever pay them enough attention to be able to *name* them. Locke does assert that in the reception of ideas 'the understanding is merely passive', but he also allows that attention, as well as repetition, helps 'much to the fixing any ideas in the memory' (*Essay* II.x.3).

The 'retention' of ideas in the memory, therefore, is a necessary condition of discursive thought, and its description significantly echoes Hobbes' account of memory as 'decaying sense'. What decay – 'it may seem probable' – are images in the brain, and hostility to the separation of intellect from imagination pervades the *Essay.* Descartes' famous argument for such a separation – that we can accurately reason about a chiliagon although we

cannot form a distinct image of it – is directly rebutted: the reasoning is made possible by our precise idea of the number of the sides (itself dependent on the technique of counting), not by a clear and distinct idea of the shape. 'Clear' ideas are, by definition, such as we receive 'in a well-ordered sensation or perception'. Locke's treatment of abstraction accords with such express sensationism. 'Abstract ideas' are particulars, universal only in 'the capacity, they are put into . . . of signifying or representing many particular things' (*Essay* III.iii.11). Locke means that in abstract thought the mind relates to, and employs, sensory images in a certain way, not that it manufactures sense-transcendent objects of intellect. Abstract ideas are what we have *distinctly* before the mind in general thought, but distinctness may be achieved by 'partial consideration', not absolute separation: 'Many ideas require others as necessary to their existence or conception, which are yet very distinct ideas. Motion can neither be, nor be conceived without space' (*Essay* II.xiii.11–13). The very abstract ideas of *being* and *unity* are ideas of anything whatsoever considered as existing, or as one. Geometry gave Locke his paradigm of 'perception of the relation between ideas'. But where Cartesians saw the role of geometrical diagrams to be the stimulation of intellectual ideas, for Locke, as for Hobbes, the object of reasoning and source of 'evidence' is the diagram itself, whether actual or imagined. (Kant's 'intuition' owes something to Locke.) Given these structural features of his theory, it seems undeniable, as some have denied, that Locke's ideas are essentially sensory (or reflexive) images (see HOBBES, T. §4; KANT, I. §5).

4 Five sorts of idea

Book II of the *Essay* presents an alternative to Aristotle's doctrine of categories, the traditional typology of entities capable of being named or predicated (see ARISTOTLE §7). That Locke's classification is of *ideas* rather than of *things* stresses that the categories are purely conceptual. He identifies five broad types: simple ideas, ideas of simple modes, ideas of mixed modes, ideas of substances and ideas of relations. Simple ideas come first in the Lockean order of knowledge, as substances come first in the Aristotelian order of being. Simple ideas are necessarily given in experience, whereas complex ideas can be constructed by 'enlarging' ('repeating') or 'compounding' simple ideas. Ideas of relations result from 'comparing' ideas. 'Abstracting' is more a matter of focusing on an idea or, better, an aspect of an idea, whether given or constructed, than of creating a new one (see §3). Locke sometimes acknowledges that the overarching compositional model is problematic in its application, but it is put into doubt even by his formal introduction of the notion of a simple idea. The ideas of the sensible qualities of a body, Locke claims, though produced by the same body, in some cases by the same sense, are evidently distinct from one another, each being 'nothing but *one uniform appearance*, or conception in the mind' (*Essay* II.ii.1). Yet to ascribe the conceptual distinctions between, for example, a thing's shape, its motion and its colour to a primitive articulation of *appearance* is to beg a crucial question.

Under the topic of simple ideas Locke expounds his famous distinction between primary and secondary qualities (*Essay* II.viii). Since the cause of a simple idea may be quite different in character from the idea itself, we should distinguish the idea in the mind from the corresponding quality (that is, the power to cause the idea) in bodies. Certain qualities, however, are necessary to our conception of bodies as such. These are the primary qualities, 'solidity, extension, figure, motion, or rest, and number', just those which figured in corpuscularian speculations. Locke's proposal (displaying the tension, described in §3 of this entry, between two conceptions of representation) is that in the perception of a primary quality the represented cause, the basis of the power in the object, is qualitatively *like* the idea caused: 'A circle and square are the same, whether in idea or existence' (*Essay* II.viii.18). Only this will allow that the action of external bodies on the senses is 'by *impulse*, the only way which we can conceive bodies operate in' (*Essay* II.viii.12) – an appeal to the seventeenth-century commonplace that mechanical explanations are peculiarly intelligible. But then ideas of 'colours, sounds, tastes, etc.', Locke's 'secondary qualities', must also be mechanically stimulated. Hence secondary qualities 'are nothing in the objects themselves, but powers to produce various sensations in us by their primary qualities, i.e. by the bulk, figure, texture, and motion of their insensible parts' (*Essay* II.viii.10). Ontologically they are in the same boat as the power of fire to cause pain or, indeed, its power to melt wax.

The idea of power itself Locke attributes to experience of regular patterns of change, giving rise first to expectations that 'like changes will for the future be made in the same things, by like agents, and by the like ways', and then to the thought that in one thing exists the possibility of being changed and in another 'the possibility of making that change' (*Essay* II.xxi.1). So we form the idea of power, active and passive: the power of fire to melt wax and the power of wax to be melted are aspects of fire and wax known and identified only through their joint effect. The idea of power is thus a place-marker for attributes which could in principle be known more directly.

The ideas or experiences of pleasure and pain are important simple ideas, since they are responsible for our ideas of good and evil, and are 'the hinges on which our passions turn' (*Essay* II.xx.3). (This hedonistic theory of motivation and value is examined in §9 of this entry.)

'Simple modes' constitute another problematic category. Locke starts with modes of extension, the subject-matter of geometry, with which he compares modes of duration. Here his thesis is that we acquire ideas of particular modes of extension (that is, determinate lengths and figures) or duration (that is, periods) in experience, and can then repeat (or divide) them so as to construct ideas of possible lengths, figures or periods not previously experienced. Roughly, 'modification' here is compounding like with like. The same model supplies Locke's account of ideas of numbers, achieved by the repetition or addition of units, aided and ordered by the linguistic technique of counting. Yet he also recognizes qualitative simple modes, effectively conceding that ideas of different 'shades of the same [experienced] colour' are constructible. Even with quantitative 'modes', where the 'repetition' model has some plausibility, it is problematic what is a simple idea. The idea of determinable *extension* is a plausible candidate, with its determinates as 'modes', but the repetition model presupposes simple units. Locke impatiently responds that the smallest sensible point 'may perhaps be the fittest to be consider'd by us as a *simple idea* of that kind' (*Essay* (5th edn) II.xv.5n.), but he was evidently more concerned to argue that ideas of novel determinate figures are *somehow* constructible from what has been given, and so to subvert a Platonic-Cartesian argument for innateness, than to insist on the adequacy of a rigid compositional model.

Another target in Locke's account of simple modes is Descartes' conceptual identification of space and matter in the thesis that the essence of matter is extension. For Locke, both the essence of matter and the nature of space are unknown. He argues that our idea of a vacuum is not contradictory, since our ordinary idea of body includes solidity as well as extension, but he declines to choose between relational and realist theories of space. Yet comparison of the *Essay* with earlier notes and drafts indicates that, having first held a Hobbesian relational view, Locke came gradually to favour a realism close to that of Newton (see Descartes, R. §§8, 11; Newton, I.).

Ideas of mixed modes arise with the combination of unlike simple ideas, as in the idea of a rainbow. But Locke's paradigms are ideas of human actions and institutions, the materials of demonstrative moral and political theory. Like ideas of geometrical figures, ideas of mixed modes can properly be formed without regard to what exists. Ethical thought is none the worse for being about a virtue or motive or political constitution which is nowhere actually instantiated. Ideas of substances are different, for they concern the real rather than the ideal: 'When we speak of *justice*, or *gratitude*... our thoughts terminate in the abstract ideas of those virtues, and look not further; as they do, when we speak of a *horse*, or *iron*, whose specific ideas we consider not, as barely in the mind, but as in things themselves, which afford the original patterns of those ideas' (*Essay* III.v.12). Moreover, whereas ideas of substances are formed on the presumption that the complex idea represents a really or naturally united thing, the unity of mixed modes is essentially conceptual. Indeed, 'Though... it be the mind that makes the collection, tis the name which is, as it were the knot, that ties them fast together'. Different languages slice up the field of human life and action in different ways, determined by the practices and priorities of the communities that speak them. This thesis can be extended to natural modes such as freezing, since even here it is the term tied to a striking appearance, not a natural boundary, which slices out the particular process from the general process of nature. That, Locke plausibly assumes, is not how it is with horses.

The chief thought behind Locke's somewhat confusing account of ideas of substances is that our idea of a thing or stuff is a compound of ideas of its qualities, but the thing itself is not a compound of qualities (*Essay* II.xxiii). The substance–accident structure is a feature of our ideas and language, not a structure in reality. It is a feature which marks our ignorance of the underlying nature of things, since we always conceive and talk of a substance as a *thing* possessing certain qualities, that is, as a '*substratum*, in which [the qualities] do subsist, and from which they do result, which therefore we call substance'. The mistake of dogmatic philosophers is to think that they can form *simple* conceptions of substances matching their unitary natures. Aristotelians are so misled by language that, just because, 'for quick despatch', we employ one name, 'gold' or 'swan', they think it a 'simple term' corresponding to a 'simple apprehension'. Cartesians take the simple essences of matter and spirit to be extension and thought. Yet so far are we from catching the nature of any thing in our *complex*idea of it that, if it is asked what the subject is of the qualities by which we define it (the colour and weight of gold, for example), the best answer we can give is 'the solid extended parts', that is, the mechanistic 'corpuscularian' hypothesis as advanced by Boyle. If it is asked in turn 'what it is, that solidity and extension inhere in,' we can only say, 'we know not what'. Our idea

of the substance is of 'nothing, but the supposed, but unknown support of those qualities, we find existing, which we imagine cannot subsist, *sine re substante*, without something to support them'. Such an idea is 'obscure and relative'. Ideas of specific substances are 'nothing but several combinations of simple ideas, co-existing in such, though unknown, cause of their union as makes the whole subsist of itself' (*Essay* II.xxiii.6). Locke's point is that no theory, not even the corpuscular hypothesis, gives an account of the ultimate nature of things.

Finally come ideas of relations – father, son-in-law, enemy, young, blacker, lawful and so on (*Essay* II.xxv–xxviii). Like ideas of modes, ideas of relations can properly be constructed without regard to reality, in particular if they are conventional relations. Adequate ideas even of natural relations, Locke claims, are possible without adequate ideas of the things related: we can grasp the essence of fatherhood without knowing the essence of man or even the mechanisms of reproduction. His point is that the biological details are irrelevant to the rights and duties of a father – a question rationally determined in his own attack on patriarchalism in *Two Treatises*. From this point of view, relations are theoretically close to modes. Yet Locke does allow certain relations to have peculiar ontological significance. Causal, spatial and temporal relations are universal relations which pertain to all finite beings. Identity and diversity are so too: a thing is diverse from anything existing in a different place at the same time, 'how like and indistinguishable soever it may be in all other respects', and the continuity of individual substances is spatio-temporal. The last important type of relations to be picked out for special discussion is that of moral relations, or the relations of actions to some law 'whereby good or evil is drawn on us, from the will and power of the law-maker' (*Essay* II.viii.5).

5 Substances, mixed modes and the improvement of language

On Locke's account of communication (*Essay* III.i–ii), names should, by common convention or special agreement, excite in the hearer's mind just the same ideas as they are associated with in the speaker's mind. Collaborative progress in the sciences depends on 'clear and distinct' or 'determined and determinate' ideas – that is, on consistent and agreed association of ideas and words (*Essay* II.xxix; compare 'Epistle to the Reader'). Locke's discussion of language is shaped by his belief that these conditions of the transference of knowledge were in his time commonly unsatisfied, especially in two domains. First, there was no agreed classification of 'substances' (living things and chemicals) based on careful observation and experiment. Second, the ideas associated with the names of mixed modes often varied both in the usage of different people and in that of the same person at different times. Two mistakes in particular disguise these shortcomings of language. The first is the assumption that a common set of words ensures a common language in the full sense, with a shared set of meanings. So people may argue about 'honour' and 'courage' without realizing that they mean different things, or nothing at all, by the words. The second mistaken assumption is that words have meaning by standing for things directly, as if the meaning of 'salt', 'gold' or 'fish' were fixed demonstratively, by what is named. The first assumption chiefly corrupts our thought about mixed modes, the second relates 'more particularly, to substances, and their names' (*Essay* III.ii.5). Locke's radical and influential views about the latter will be considered first.

The 'idea of substance in general' employed in ideas of specific substances is the idea of something unknown underlying the attributes known by experience (see §4 of this entry). Many have objected, following Leibniz, that here Locke confusedly postulates ignorance of the subject of attributes which is not ignorance of attributes of the subject. Yet he holds that our ignorance of 'the substance of body' and 'the substance of spirit' is an ignorance of the *natures* of these things – ignorance manifested in our inability to understand the internal cohesion or (he adds in later writings) mutual attraction of bodies, or to explain what thinks in us, and how it does so. His approval of the corpuscularian hypothesis and Newton's mechanics is qualified – the best available physical theory leaves too much unexplained to be the whole truth (Newton did not disagree). The idea of substance is a place-marker for essences which are unknown, but knowable, if possibly not by human beings (see Newton, I.).

One feature of Locke's theory which has made difficulties for the present interpretation is the distinction he makes between substance and 'real essence'. The real essence of a thing, Locke says, may be taken for 'the very being of a thing, whereby it is what it is', the 'real internal, but generally in substances, unknown constitution of things, whereon their discoverable qualities depend' (*Essay* III.iii.15). Nevertheless, '*essence*, in the ordinary use of the word, relates to sorts' (*Essay* III.vi.4). Species and genera, or sorts of things, Locke asserts, are creatures of the understanding, with membership determined by abstract ideas made on the basis of experienced resemblances, not by the presence in each of a specific form, or by

a common derivation from a divine archetype. Ultimately it is a matter of arbitrary definition which observable resemblances we count as necessary for membership of this or that named sort. It is not just that specific real essences are unknown, since (Locke argues) even if we did know the real constitution of things as well as clock-makers know the works of clocks, it would still be up to us where to draw the boundaries between species, and what to include in our abstract ideas or 'nominal essences'. The real essence of a species can therefore only be 'that real constitution . . . which is the foundation of all those properties, that are combined in, and are constantly found to co-exist with, the *nominal essence*' of the species (*Essay* III.vi.6). Here, the model is that of a universal matter determinately modified as a variety of particles interacting mechanically so as to constitute the material things of ordinary experience. Since at the fundamental level these observable quasi-machines differ from one another merely quantitatively, and can do so by indefinite degrees, there are no absolute boundaries among them. There are only the discernible resemblances and differences consequent on their underlying mechanical differences – 'the wheels, or springs . . . within'. Even more certainly our actual classification is not based on knowledge of any such boundaries. Talk of the real essence of a species, and the distinction between its 'properties' and its 'accidents' ('properties' flowing from the essence), are therefore, contrary to Aristotelian assumptions, *de dicto* and relative to the nominal essence defining the name of that species (see Aristotle §8; De re/de dicto; Essentialism).

This conception of a real essence assigns it a role closely related to that of substance. What, after all, is the 'unknown cause of the union' of any of the 'combinations of simple ideas' by which 'we represent particular sorts of substances to ourselves', if not the real essence underlying the nominal essence in question? Yet Locke sometimes distinguishes both the notion and knowledge of real essence from the notion and knowledge of substance. That is not, however, because the 'substance' is an irremediably unknown subject underlying even essence, but because it is the common stuff of a variety of species of things, 'as a tree and a pebble, being in the same sense body, and agreeing in the common nature of body, differ only in a bare modification of that common matter' (*Essay* II.xiii.18). The unknown modification is the specific 'real essence', and the equally unknown general nature of matter is the 'substance'. Locke also envisages deeper differences of kind between substances: 'God, spirits and body' are all 'substances' only because we think of each of them indeterminately as *something*, not because of a shared nature. But by the same token we distinguish spirit and body only because we cannot understand how matter could think, not because we can grasp their separate essences, as Descartes had supposed (see Descartes, R. §8). Indeed, since we are equally unable to understand how spirit and body might interact, or how spirits could occupy places, the issue between materialist and immaterialist accounts of minds is for Locke undecidable, and at best a matter for speculation.

Locke's corpuscularian conception of a world of machines, resembling and differing from one another by continuous degrees, is consonant with his independent epistemological conviction that names have meaning only through association with 'ideas', rather than directly with 'things as really they are'. Together they motivate his programme for improving natural classification which advocates, not the allegedly impossible Aristotelian ideal of identifying the natural hierarchy of genera and species, but general agreement on a practically useful way of gathering and ordering the things in the world, taking into account such dependable concomitances of qualities and powers as appear to careful observation and experiment. Locke saw the future of biology and chemistry – and even of mechanics – in descriptive 'natural history', justifiable as a useful, orderly record of dependable means to ends but falling short of systematic 'science'. Despite its apparent pessimism, his view has survived in biological taxonomy as a continuous tradition of scepticism as to the reality of our taxonomical divisions. In semantic theory, Locke's broad conception of how the names of substances have meaning has only recently been eclipsed by a quasi-Aristotelian view (see Kripke, S.A.; Putnam, H.).

Locke saw equal need for a programme of agreeing definitions in ethics, where his target is less the notion that moral and political terms name independent realities, than the assumption that the very existence of a word in a language ensures that it has a fixed, common meaning. 'Common use', Locke concedes, 'regulates the meaning of words pretty well for common conversation' (*Essay* III.ix.8) – for the 'civil' rather than 'philosophical' use of words. But where precision is required, as in the establishment or interpretation of a law or moral rule, reliance on ordinary usage leaves us vulnerable to the trickery of rhetoricians who prove bad qualities good by shifting the meaning of terms; or to the subtleties of interpretors, whether of civil or revealed law, who render unintelligible what started off plain. The remedy is to give the names of virtues and vices, and of social actions, roles and relations the fixed and unequivocal definitions necessary for a

clear and unwavering view of right and wrong, 'the conformity or disagreement of our actions to some law'.

6 Knowledge and belief

Like Platonists and Cartesians, Locke drew a strong distinction between knowledge and belief (also called opinion, judgment, or assent), but the ground and placing of this division between two forms of propositional 'affirmation' differed from theirs fundamentally. As the distinction is expounded in Book IV of the *Essay*, universal knowledge or 'science' does not have special objects, whether a transcendent intelligible world in the mind of God or innate intellectual ideas. Its difference from general belief lies in the way in which ideas are related in the mind. In universal knowledge, the 'connection and agreement, or disagreement and repugnancy' of ideas is 'perceived', whereas in belief it is 'presumed' on the basis of 'something extraneous to the thing I believe'. To follow a proof gives knowledge of the conclusion, whereas to accept the conclusion on the authority of a mathematician constitutes only belief. Similarly in the case of 'sensitive knowledge' of particular existence, what we ourselves perceive we know to be so, but what we infer, or accept on testimony, we merely believe.

Knowledge, as well as assent, is subject to 'degrees': there are degrees, not only of probability, but of 'evidence'. The first degree of knowledge is intuitive knowledge, in which the mind 'perceives the truth, as the eye doth light, only by being directed toward it'. Intuition 'leaves no room for hesitation, doubt, or examination'. The second degree is demonstrative knowledge, where the truth is perceived by the aid of one or a chain of 'intermediate ideas'. Doubt or mistake is possible at any point in the sequence with respect to connections not currently in view. Hence, 'Men embrace often falsehoods for demonstration'. Locke's chief model for 'intermediate ideas' is geometrical: for example, the lines employed in the intermediate steps of the Euclidean proof which allow us to see that the angles of a triangle are equal to the angle on a straight line. Although his conception of intuition can seem Cartesian, the profound difference is that, for Locke, ideas which are objects of intuition are essentially a product of sense (including reflection) and imagination. As *Draft B* puts it, the angles and figures I contemplate may be 'drawn upon paper, carved in marble, or only fancied in my understanding' (*Drafts* vol. 1: 152). Consequently Locke often talks as if we can *literally* perceive a necessary relation between ideas. Another difference from Descartes, as also from Hobbes, is that he rejects the pretensions of proposed analytical methods to uncover self-evident principles from which the phenomena can be deduced.

The third degree of knowledge is sensitive knowledge of the existence or 'co-existence' of qualities in external things. Locke's first introduction of this category seems tentative, even an afterthought, as if it is called knowledge only by courtesy. In order to fit his main definition of knowledge it has to be interpreted as the perception of the agreement of ideas of sensible qualities with the idea of existence, an analysis Locke unsurprisingly declines to develop. Yet 'sensitive knowledge of existence' does straightforwardly satisfy his other definition of knowledge: what is known in sensitive knowledge (that is, that something external is causing an idea of sense) is known directly, 'perceived' and not inferred (see §2 of this entry). Locke was writing in a context in which, despite Gassendi's Epicurean claim that sensory knowledge is the most evident of all, it was widely assumed that knowledge in the full sense comprises only knowledge of necessary first principles, demonstrated 'science', and perhaps reflexive knowledge. Locke wanted both to concede to orthodoxy that the evidence and certainty of our sensory knowledge is not as high as that of intuition and demonstration, and to insist that, nevertheless, 'sensitive knowledge of existence' does give a degree of immediate certainty and 'deserves the name of knowledge'.

Knowledge is also categorized in terms of four propositional relations (forms of 'agreement') between ideas, namely 'identity (or diversity)', 'relation', 'necessary connection or coexistence' and 'existence' (*Essay* IV.i). By 'identity' Locke intends tautologies such as 'Gold is gold' and 'Red is not blue'. Intuitive knowledge of such identities is achieved simply by discerning ideas. The category also includes such truths as 'Gold is a metal' or 'Gold is malleable', when the property predicated is included in the thinker's definition of gold. Thus 'identity' covers all and only 'trifling' or 'verbal' propositions (see §2 of this entry).

The categories, 'relation', 'necessary connection or coexistence', and 'existence', on the other hand, together include all 'instructive' propositions. The category, 'relation', in part a response to Locke's earlier difficulty over the informativeness of mathematics (see §2 of this entry), also marks his rejection of analytical methods in science. As well as geometrical axioms and theorems, 'relation' presumably includes more exciting Lockean principles: as that, if anything changes, something must have a power to make it change; that, if anything exists, something must have existed from eternity; and that a maker has rights over his artefact. Categorical propositions about natural things,

however, fall either under 'existence' or under 'necessary connection or coexistence'. Our own existence is known intuitively, God's existence demonstratively (Locke employs an idiosyncratic hybrid of the cosmological and teleological proofs), and, as discussed, the existence of bodies by sense. The category 'necessary connection or coexistence' owes its disjunctive name to a rather complicated relation between particular and universal propositions. Particular *coexistences* are perceived by sense, for example, when we simply observe that yellowness, heaviness and the metallic qualities coexist in a particular subject together with malleability (that is, that this gold is malleable), without perceiving *necessary connections* between them. Locke assumes, however, with most mechanists, that necessary connections do hold between universally coexistent properties even if we cannot perceive or grasp them. Since he contends that no natural science based on the essences of substances has been achieved, he offers only very limited examples of perceived necessary connections, as 'whatever is solid is impenetrable' and 'a body struck by another will move'. (According to the short, posthumously published *Elements of Natural Philosophy*, the laws of inertia are evidently necessary, but the law of gravity is based only on experience.) In the absence of knowledge, beliefs in universal coexistences (for example, that all gold dissolves in aqua regia), when we *presume* unperceived connections, may be inductively based on sensitive knowledge of particular coexistences. That is descriptive natural 'history', not 'science'. In general, if the idea of a particular quality is deducible from the idea of a substance, that is only because the predication of that quality is an identity: that is, universal propositions about substances, if certain, are 'trifling' and, if 'instructive', are uncertain (see §2 of this entry). In contrast, instructive a priori sciences are possible just because their objects are constructed by us: our ideas of simple or mixed modes, formed without essential reference to actuality, themselves constitute the subject-matter of mathematics and ethics. In other words, these demonstrative sciences are possible, as natural science is not, just because they deal, hypothetically, with abstractions.

The degrees of assent are 'Belief, Conjecture, Guess, Doubt, Wavering, Distrust, Disbelief, etc.' (*Essay* IV.xvi). Probability is 'the measure whereby [the] several degrees [of assent] are, or ought to be regulated'. When assent is unreasonable, it constitutes 'error'. Reasonable assent is regulated according to the proposition's conformity with the thinker's own experience or the testimony of others. The proposition may concern 'matters of fact' falling within human experience, or else unobservables lying 'beyond the discovery of our senses'. Locke identifies four broad degrees of probability with respect to 'matters of fact': (1) when the general consent of others concurs with the subject's constant experience; (2) when experience and testimony suggest that something is so for the most part; (3) when unsuspected witnesses report what experience allows might as well be so as not; and (4) when 'the reports of history and witnesses clash with the ordinary course of nature, or with one another' – a situation in which there are no 'precise rules' for assessing probability. Finally, with respect to unobservables, 'a wary reasoning from analogy' with what falls within our experience 'is the only [natural] help we have' and the only ground of probability (see DESCARTES, R. §4). Although Locke, in striking contrast to Descartes, brings probability into the centre of epistemology, 'belief' is always treated as a practical surrogate for 'knowledge', and he takes induction itself to be grounded on the assumption of underlying, unknown necessary connections: 'For what our own and other men's constant observation has found always to be after the same manner, that we with reason conclude to be the effects of steady and regular causes, though they come not within the reach of our knowledge' (*Essay* IV.xvi.6).

Another deliberate and radical difference from Descartes relates to the role of will in cognition. For Locke, knowledge is like sense perception: we may choose where and how hard to look, but we cannot then choose what we see. Belief is similar: 'Assent is no more in our power than knowledge.... And what upon full examination I find the most probable, I cannot deny my assent to' (*Essay* IV.xx.16). Yet we are morally responsible for both error and ignorance in so far as it results from our not employing our faculties as we should. In a number of chapters of the *Essay*, Locke examines the causes of error, finding them, with many writers of his time, in the same appetites, interests, passions, wayward imaginings and associations of ideas as may motivate voluntary actions. Linguistic confusion, and its deliberate exploitation (see §5 of this entry), sometimes plays a role, and sometimes, like MALEBRANCHE and others, Locke has direct recourse to physiology, explicitly merging his explanations of error with explanations of madness. In contrast to Hobbes, he places the merely habitual 'association of ideas' in the pathology of 'extravagent' thought and action: 'all which seems to be but trains of motion in the animal spirits, which ... continue on in the same steps ... which by often treading are worn into a smooth path, and the motion in it becomes easy and as it were natural' (*Essay* II.xxxiii.16). But culpable error arises, on Locke's official view, when we 'hinder both knowledge and assent, by stopping our enquiry,

and not employing our faculties in the search of any truth' (*Essay* IV.xx.16). It is the failure to use our power to pause for 'full examination' which leaves a space for beliefs motivated by interests and passions. But this two-stage model – the first stage voluntary, the second involuntary – proves too difficult to maintain, and sometimes passions and interests are taken to act on the will *between* inquiry and judgment, by distorting our 'measures of probability' themselves. Locke's approach is more commonsensical than that of Descartes, but the psychology of motivated error is a hard nut which he also failed to crack.

7 Faith, reason and toleration

Locke's views on belief, probability and error owed much to traditional philosophy of religious belief, and to the great debate of his century about the relationship between faith and reason. He was strongly influenced by writers in the Anglican 'probabilist' tradition, who argued for toleration within the Church with respect to all but an essential core of Christian dogma. William Chillingworth had rejected as absurd the traditional conception of a moral requirement to have 'faith' in the sense of a conviction equal to that of knowledge but beyond what is rationally justified. To recognize a proposition as probable to a certain degree is to believe it just to that degree. Revelation therefore cannot be a basis for belief distinct from probability, but is something the significance of which has to be rationally assessed, capable at best of increasing the probability of certain propositions. Similarly for Locke, when revelation grounds belief that would otherwise be improbable, that is just one natural reason outweighing another: 'it still belongs to reason to judge of the truth of its being a revelation, and of the signification of the words, wherein it is delivered' (*Essay* IV.xviii.8). For if 'reason must not examine their truth by something extrinsical to the perswasions themselves; inspirations and delusions, truth and falshood will have the same measure' (*Essay* IV.xix.14).

Accordingly, like Chillingworth, More and others, Locke combined a purportedly reasonable acceptance of the Bible as revelation with a critical approach to its interpretation, taking into account that it was written by men in particular circumstances. An alleged revelation which conflicts with what is naturally evident loses its claim to be revelation. Certain revealed truths (such as the Resurrection) lie 'beyond the discovery of our natural faculties, and above reason', but Locke had little time for mysteries: 'to this crying up of faith, in opposition to reason, we may, I think, in good measure, ascribe those absurdities that fill almost all the religions which possess and divide mankind' (*Essay* IV.xviii.7, 11). Locke took the existence of God and the content of moral law to be demonstrable by reason, and, according to *The Reasonableness of Christianity* and its *Vindications*, the only essentially revealed truth of the New Testament is that Christ is the Messiah, promising forgiveness of sins to those who sincerely repent and do their imperfect best to keep the law of nature. The Bible also makes that law plain to those without the leisure or capacity to reason it out – a difficult enough task for anyone, as Locke ruefully acknowledges. The meaning of scripture is thus for Locke primarily moral, and the 'truth, simplicity, and reasonableness' of Christ's teaching is itself a main reason for accepting it as revelation. Saving faith involves works, not acceptance of 'every sentence' of the New Testament under this or that preferred interpretation.

Much the same goes for immediate revelation. Even the genuinely inspired would need proofs that they really were inspired, and the errors of commonplace 'enthusiasm' are ascribed, as by More, to physiology, 'the conceits of a warmed or overweening brain'. The advocate of immediate personal revelation over reason 'does much what the same, as if he would persuade a man to put out his eyes the better to receive the remote light of an invisible star by a telescope' (*Essay* IV.xix.4). Divine illumination necessarily depends on, and is not separable from, the natural light – 'reason must be our last judge and guide in everything'. Locke echoes Chillingworth's basic principle: the lover of truth, unbiased by interest or passion, will not entertain 'any proposition with greater assurance than the proofs it is built upon will warrant'. The implication of this standard, in the actual circumstances of life, is toleration: 'For where is the man, that has incontestable evidence of the truth of all that he holds, or of the falshood of all he condemns; or can say, that he has examined, to the bottom, all his own, or other men's opinions?' (*Essay* IV.xvi.4).

Locke's *Letter on Toleration*, the mature fruit of considerably more unpublished writing directly on the issue, links his epistemology with his political thinking. Belief is not something that can be commanded or submitted to the authority of the government, whose concern is not with saving souls but the preservation of property. Necessarily each individual must judge as they see fit, and the truth needs no help, having its own efficacy. But the right to toleration is nevertheless viewed in the context of the right and duty to seek salvation and true doctrine without harm to others, harm which is at least threatened by all who deny the authority either of moral law or of the established government. Atheists therefore forfeit the right in principle, and Roman Catholics as a matter of political fact. (See Socinianism.)

8 Personal identity

The main aim of the chapter of the *Essay* entitled 'Of Identity and Diversity' (II.xxvii) is to explain how immortality is compatible with materialism. In order to maintain an agnostic neutrality on the question of the immateriality of the soul, Locke had, first, to rebut the Cartesian claim that self-awareness supplies a clear and distinct idea of a simple, continuously existing substance; and, second, to show that the metaphysical issue is irrelevant to 'the great ends of morality and religion' (*Essay* IV.iii.6). He argues that, although the moral agent is indeed the continuously existing, rational, self-aware subject of consciousness, the 'person', the identity of this subject over time, is determined by the continuity of unitary consciousness itself, not the continuity of an immaterial soul. Locke can therefore accept the Resurrection and Last Judgment as tenets of his 'reasonable' Christianity, without commitment to dualism, on the supposition that the consciousness of the resurrected person is continuous, through memory, with that of the person who died. This conclusion avoids an objection to his concept of demonstrative ethics as a science of modes, that morality relates to 'man', a substance, not a mode. His response is that morality concerns, not 'man' as a biological species, but 'man' as rational, the 'moral man', indeed all rational beings. 'Person', as he puts it, is a 'forensic term'.

Locke's argument starts from the claim that questions of identity over time are always questions as to the continuous existence in space of something of a certain kind, and that difficulties may be avoided by 'having precise notions of the things to which it is attributed'. The identity of non-substances is parasitic on that of substances: 'All other things being but modes or relations ultimately terminated in substances', their identity will be determined 'by the same way' (*Essay* II.xxvii.2). Locke holds that events and processes ('actions') are not strictly identical from moment to moment, each part of what we consider one process being distinct from every other part. Substances, however, genuinely continue to exist from moment to moment. The identity of 'simple substances' – material atoms and the presumed simple 'intelligences' – is straightforward. Each excludes others of the same kind out of its place by its very existence – a principle definitive of identity. But difficulties arise with compound substances. Strictly, a body composed of many atoms is the same just as long as the same atoms compose it – yet 'an oak, growing from a plant to a great tree, and then lopped, is still the same oak'. Locke's explanation is that 'in these two cases of a mass of matter, and a living body, *identity* is not applied to the same thing' (*Essay* II.xxvii.3). Although he does not clearly distinguish the two views, he seems to hold individuation, rather than the identity-relation, to be kind-relative. A plant or animal is not just 'a cohesion of particles anyhow united', but such an organization of parts as enables the continuation of its characteristic life, for example, as an oak. In fact the *species* of the living thing is irrelevant to Locke's theory (fortunately, given his view that the definition of 'oak' will differ from speaker to speaker). The essential claim is that life is a principle of unity and continuity distinct from simple cohesion, thus allowing a living thing and the mass of matter that momentarily composes it so to differ in kind as to be capable of occupying the same place at the same time.

Locke defines *person* as 'a thinking intelligent being, that has reason and reflection, and can consider itself as itself, the same thinking thing at different times and places' (*Essay* II.xxvii.9). His thesis is that, just as life constitutes a distinct individuative principle of unity and continuity, so does reflexive consciousness. He argues for the logical independence of the continuity of consciousness from both the continuity of substance (whether supposed material or immaterial, simple or complex) and the continuity of animal life by a series of imagined cases: for example, for someone now to possess Socrates' soul would not make him the same person as Socrates, unless he remembered Socrates' actions as his own; whereas if souls are the seat of consciousness, and the soul of a prince could migrate to the body of a cobbler, 'everyone sees he would be the same person with the prince, accountable only for the prince's actions. But who would say it was the same man?' (*Essay* II.xxvii.15). Locke viewed such cases, not necessarily as real possibilities, but as compatible with our partial understanding of things, our *ideas*: 'for such as is the idea belonging to that name [namely 'person', 'man' or 'substance'], such must be the identity'. Yet in the crucial case of the Resurrection, we are left wondering how continuous existence through time – not to speak of space – is achieved simply by a fit between present consciousness and past experience and actions. Indeed, as Berkeley and Reid argued, memory-links seem both too little and too much for the continuity of a substantial thing. Yet, despite these and other difficulties for Locke's theory, it set the agenda for subsequent discussion and versions of it still have adherents (see Personal identity).

9 Ethics, motivation and free will

With Locke's conviction that a demonstrative ethics is possible went a belief that what stood in its way was the deplorable slipperiness, openly encouraged by the practice of rhetoric, of a moral language in

which terms are not consistently tied to ideas (see §5 of this entry). Both were consonant with his apparently early conviction that Natural Law theory, as pursued by such as Hooker and Grotius, is capable of development into a full account of our duties to God and our fellows – even though he had first seen Natural Law as empirically based (see §3 of this entry). But Natural Law theory also gave him what could not be supplied by the conception of a quasi-geometrical system of rights and duties flowing from the definitions of mixed modes and relations: the conception of an unconditional obligation to act in accordance with moral principle against what we might otherwise desire (see Natural Law).

In the *Essay* the argument starts, as might be expected, with the question of how our basic concepts of value are derived from experience. Locke has no doubt about what it is in experience that makes anything matter to us. Like other empiricists of his time, he is both a psychological and an ethical hedonist. Pleasure and pain supply not only our sole motives but also our ideas of good and evil: 'That we call *good* which is *apt to cause or increase pleasure*, or *diminish pain in us; or else to procure, or preserve us the possession of any other good, or absence of any evil*' (*Essay* II.xx.1). The passions are 'modes' of pleasure and pain arising from, or involving, value-judgments: thus hope is 'that pleasure in the mind, which every one finds in himself, upon the thought of a probable future enjoyment of a thing, which is apt to delight him'; fear is 'an uneasiness of the mind, upon the thought of a future evil likely to befall us' (*Essay* II.xx.9–10). Desire is the 'uneasiness a man finds in himself upon the absence of any thing, whose present enjoyment carries the idea of delight with it' (*Essay* II.xx.6). This theory of motivation faces certain problems. First, how do we get from judgments of good and evil, of what conduces to pleasure and pain, to judgments of right and wrong, of what we morally ought or ought not to do? Second, having got there, if the passions, as modes of pleasure and pain, constitute our only motives, what passion could motivate us to do what is right? Third, in what, if anything, does choice and free will – moral agency – consist?

Locke's answer to the first question, already given in *Essays on the Law of Nature*, is that the concept of obligation comes with the relational concept of law: '*Morally good and evil* then, is only the conformity or disagreement of our voluntary actions to some law, whereby good or evil is drawn on us, from the will and power of the lawmaker; which good and evil, pleasure or pain, . . . is that we call *reward* and *punishment*' (*Essay* II.xxviii.5). Locke makes it clear that the notion of obligation presupposes the right, as well as the power of the lawgiver to legislate and punish – in *Essays* Locke's 'power' is explicitly *potestas*, authority, rather than *potentia*, mere force. There are, he says in the *Essay*, three kinds of law: divine law, the measure of sin and moral duty; civil law, the measure of crimes and innocence; and the law of opinion or reputation, the measure of virtue and vice. God legislates by *ius creationis*, the maker's right over what is made, and divine law is binding on all rational creatures capable of pleasure and pain. God's law accords with his wisdom and benevolence, so that we can know it by reflecting on what a wise and benevolent Deity would require of us. Unsurprisingly, Locke's ethics is heavily utilitarian.

The relationship between divine law and civil law, and the standing of the civil magistrate under divine law, is the subject-matter of Locke's political theory as expounded in *Two Treatises*. The notion of a 'law of reputation', sometimes called 'the philosophical law', has a more complex role in his thought. It is Locke's explanation of popular secular morality, but it also represents his view of the possibility of non-theistic philosophical systems of ethics. Roughly, the thought is that ordinary morality, sanctioned by public approval and disapproval, exists as a means to the preservation of society, itself a condition of the happiness of individuals. As arrangements differ between societies, so do their moral concepts and what counts as virtue and vice in each, although naturally there will be overlap given their shared aim of self-preservation. Since the divine law too is concerned with the good of human beings, and with self-preservation as a duty, the law of reputation will tend to coincide with divine law. In the aborted fragment of the *Essay*, 'Of Ethick in General', Locke suggests that philosophers may have some inkling of the divine law, but they confuse it with the law of reputation. Consequently their systems reduce either (like that of Hobbes) to an advocacy of what tends to the preservation of society, or (like that of Aristotle) to the elaboration of a set of definitions of the behaviour of which a particular society approves or disapproves. Locke does not deny the social importance of the law of reputation, however, and in *Some Thoughts concerning Education* he assigns a necessary role in a child's moral education to public esteem and shame. His complaint is that an explanation of moral obligation in terms of the value of certain actions to society, and the value of society to the individual, cannot explain how we may be morally obliged to do something contrary to our own felt interest – our interest, at least, in this world. Self-interest may commonly prescribe adherence to social rules, but it may not always do so. As Locke says in the *Essays on the Law of Nature* (1664) 'a great number of virtues, and the best of

them, consist only in this: that we do good to others at our own loss'.

Locke's position is, then, that in order to explain both moral obligation and moral motivation (conflated in the usual seventeenth-century notion of obligation), we need to see morality as a system of laws prescribed by a supremely rational, just and benevolent creator to whom we owe the duty of obedience as creatures, and whose power to reward and punish in the next life is capable of motivating anyone who duly considers it (see VOLUNTARISM). Like any theistic explanation of morality's binding force, this proposal is incoherent, and in its case the incoherence lies in the combination of the view that obligation is created by law with the claim that we have a natural obligation to obey the law of our creator. Locke, however, was more exercised by the problem of why consideration of the afterlife so often fails to move theists to do their duty. Indeed, he accorded the problem wider scope, since he followed Pascal in the thought that the bare possibility of there being an afterlife, given the infinite good at stake, ought in reason to motivate the Christian life (see PASCAL, B.). Locke's explanation of the human capacity to know the better and choose the worse involved a refinement of his theory of motivation which echoes his theory of error. In the first edition of the *Essay*, in the long chapter 'Of Power', he held that 'the choice of the will is everywhere determined by the greater apparent good' (*Essay* II.xxi.70). By the second, he believed that mere consideration of future benefit will not move us to action unless it gives rise to 'an *uneasiness* in the want of it' – that is, to desire. Only a present passion – and, it seems, a kind of pain – can move to present action. It may require some reflection on the situation, over and above the simple recognition of probable or possible consequences for good or ill, to bring desire up to scratch, and to 'suit the relish of our minds to the true intrinsic good or ill, that is in things'. Someone who sees the good but does not pursue it has not reflected enough: 'Morality, established upon its true foundations, cannot but determine the choice of any one that will but consider' (*Essay* II.xxi.70).

Locke's increased emphasis on the role of deliberation in his hedonistic theory of moral motivation complicates his much revised account of liberty. He adopted a self-determinist view of free will – a free action is not one that is causally undetermined, but one determined by the agent's 'own desire guided by his own judgement'. He defines 'liberty' as 'the power to act or not to act according as the mind directs' (*Essay* II.xxi.71). But another power became increasingly important to him, the power 'to stand still, open the eyes, look about, and take a view of the consequence of what we are going to do, as much as the weight of the matter requires' (*Essay* II.xxi.67), and it is in this power, he often suggests, that the liberty of rational agents really consists. The tension is unresolved, for Locke never retracts the rhetorical question to which he himself seems to have given an answer: 'For how can we think anyone freer than to have the power to do what he will?' (*Essay* II.xxi.21) (see FREE WILL).

10 Political theory

Locke's mature political theory is set out in 'An Essay concerning the True Original, Extent, and End of Civil Government', the second of *Two Treatises of Government*, the first being a point-by-point rebuttal of Robert Filmer's biblically based patriarchalism (see FILMER, R.). Locke's primary contention is that the right to govern comes with a duty to govern in the interest of the governed. Failure by the government to recognize or observe this duty creates the right to rebel. Like the Natural Law theories of Hooker, Grotius and Pufendorf on which he draws, Locke's argument moves from first principles, in effect a fragment of his proposed demonstrative ethics; but much of its richness derives from links with his practical political concerns and interests. It presents attitudes and actions attributable to Charles II and James II as a betrayal of trust, hostile to those features of the British constitution most adapted to the essential purposes of government; but he also states principles relating to property, money, social conventions, taxation, punishment, family relations, inheritance, the rights of the poor, enclosure of land, the practice and justification of colonial settlement, and more.

Filmer had argued that both political authority and property rights exist only by divine institution – by God's giving Adam dominion over the creatures, by the subjection of Eve, and by Adam's natural paternal rights over his children. Monarchs are deemed natural inheritors of Adam's rights. A part of Locke's strategy, pursued in both Treatises, against this doctrine was to drive wedges between the possession and inheritance of property and the possession and conveyance of authority, and between paternal (or, as Locke prefers, parental) authority and political authority. For example, the right of children to inherit their parents' property stems from their natural right (not just that of the eldest child) to sustenance by their parents, a right which cannot be supposed to embrace either patriarchal authority or political power. The analogy of power and property in Filmer's argument, however, was not only in relation to inheritance, for it entailed that individual ownership is simply a

grant of use by the king, making taxation – its partial withdrawal – his personal right. Locke was therefore concerned to give property a quite different role in his explanation of political society.

For Locke, government is a human invention, to which personal property is prior. In a state of nature, he argues in the Second Treatise, human beings have an obligation, in accordance with divine or natural moral law, 'to preserve the rest of mankind', their equals as creatures and servants of God, by a rational extension of their duty to preserve themselves. More specifically, 'no one ought to harm another in his life, health, liberty or possessions' (*Two Treatises* II.6). Yet, before government, 'everyone has a right to punish the transgressors of that law to such a degree, as may hinder its violation'. The 'state of nature' is not, for Locke, a merely ideal abstraction, but a historical situation in which members of simple societies have lived and still live, unless in time of war, and in which independent national governments always necessarily exist. For international relations are not governed by positive law prescribed and sanctioned by constituted authority. In this situation the victim of aggression – or indeed any onlooker, for the violation is of the natural law which maintains the welfare of all – has the right to destroy the aggressor until offered peace, reparation and security for the future. Within civil society itself this 'right of war' or self-defence exists whenever the law cannot be effectively exercised, whether in the immediate circumstances of threatened harm, or when the administration of the law is manifestly corrupt, and itself employed to commit violence and injury.

'Liberty' in the state of nature is freedom from any constraint but the moral law of nature. Under government, it is freedom from the 'arbitrary will of another man', and from any human rule but the 'standing rule . . . common to everyone of that society' *Two Treatises* II.22). (Locke sees slavery as continuation of war – it is just if the war is just, when it is in lieu of capital punishment, the justly enslaved, like criminals, being 'outside civil society'. Yet this hardly stands as an endorsement of contemporary colonial slavery – indeed Locke denies that the children of aggressors can be justly enslaved, or even disinherited.) 'Possessions' arise in a state of nature with the act of appropriation which is a necessary condition of the use of any of the comestibles naturally available to all: 'this law of reason makes the deer, that Indian's who hath killed it' (*Two Treatises* II.30). Such appropriation is an extension of the principle that 'every man has a property in his own person', and therefore in 'the labour of his body'. Consequently whatever someone has 'mixed his labour with' is his, provided that it is for use, and 'there is enough, and as good left in common for others' (*Two Treatises* II.27). This principle applies also to the enclosure of land for agriculture, which vastly increases its productivity. With land, as in all else, 'labour makes the far greatest part of the value of things, we enjoy in this world' (*Two Treatises* II.42). Nevertheless, before the conventional use of money, no one would have either motive or right to produce more than they could use, give to others or exchange before it spoils. To take something from the common store and let it spoil is against natural law. Money, however, is an artifice which modifies the whole nature of property rights, since it can be stored indefinitely without spoiling. Money makes it worthwhile to exploit land fully, and supplies a just means of keeping the product. So far from wronging others, enclosure and improvement greatly increase 'the common stock of mankind', making 'a day labourer in England' better off than a king among the (Native) Americans (*Two Treatises* II.41). Significant disparity of wealth becomes both possible and morally justified, on the assumption that none will suffer absolutely (in a Board of Trade paper Locke simply assumed that everyone should have 'meat, drink, clothing and firing . . . out of the stock of the kingdom, whether they work or no'. But the effect is greatly to complicate the administration of the law of nature, and to render its application uncertain, as well as to encourage its breach through greed.

All this, on top of the standing need for both impartiality and sufficient force to punish malefactors, necessitates government. The chief role of such government is to determine rules to order and preserve property. Common defence is another imperative. Government with such legislative and executive powers comes into existence when people, by consent, resign their 'executive power of the law of nature . . . to the public' (*Two Treatises* II.89). Each individual member gives consent, but is thereafter bound to move with the majority. To the objection that no such agreement has ever taken place, Locke argues that, although 'government is everywhere antecedent to records', cases abound of new or primitive societies with elected leaders. In the first instance, this may be 'some one good and excellent man' or effective general, or indeed the father of a familial group, but experience of unrestrained monarchy encourages legislatures of 'collective bodies of men', with none above the law. In any case, consent is normally tacit, and given in the active enjoyment of the benefit of the law, whether by possession of land or 'barely travelling freely on the highway'. Such tacit consent obliges obedience to the law, although the obligation lasts only as long as the enjoyment, leaving the individual free to give up the benefit and 'incorporate himself

into any other commonwealth'. Express consent, however, binds the individual to obey and assist a particular government until its dissolution (or breach of trust).

A subject's ultimate obligation is to the supreme power, which is the legislative, itself bound by the law of nature in its choice of means, 'established and promulgated laws', for the preservation of its subjects and their property. Given this role, a government has no right to tax its subjects without their consent 'either by themselves, or their representatives chosen for them'. In order to minimize the risk of the legislative acting in its own, rather than in the public interest, it is best that it be an assembly which meets from time to time, separate from the continuously acting executive. A third, 'federative' power of war, peace and alliances is less easily directed by antecedent laws than the executive power, but falls naturally into the same hands, since both depend on public force. Locke allows some qualification of the absolute separation of powers, and subordination of the executive to the legislative, in recognition of the 'prerogative' power of the English king to dissolve and convene Parliament as circumstances require, and to employ discretion in the execution of the laws (Locke notes without express approval the power to veto legislation). Yet Locke sees prerogative as justified only as falling under 'the power of doing public good without a rule' in the face of unforeseen circumstances, and as dangerously capable of abuse. Its continuous employment contrary to the public good, for example by refusing to convene the legislative or by tampering with the rules for its election, makes the king himself a rebel and destroyer of the government, at war with his own subjects, returning them to a state of nature with a right to set up a new government.

11 Influence

Perhaps no modern philosopher has had a wider influence than Locke. His immediate achievement was, with Newton, to bring to an end the dominance within Europe of Cartesian science and philosophy, unseating the broadly Neoplatonic notion that mind and world share a common, divinely imposed structure, in favour of a modest, naturalistic conception of human capacities. Careful observation and systematic description are more valuable than the construction of hypotheses purportedly achieved by super-experiential means. Locke's own 'historical' treatment of the mind as a familiar, describable but deeply mysterious part of nature had considerable influence on European thought. His theory of classification influenced later taxonomy, and his brilliantly original theory of personal identity is still a standard text for philosophical discussion. His philosophy was one of the chief influences on Kant, but can still suggest an alternative to Neo-Kantian conceptualism. If his ethical theory appears to be the last throes of early modern natural law theory rather than a new beginning, within that structure he enunciated a classic justification of responsible, tolerant and broadly democratic political society which has remained a major resource for political theorists ever since.

LOGIC, PHILOSOPHY OF

Introduction

Philosophy of logic can be roughly characterized as those philosophical topics which have emerged either from the technical development of symbolic (mathematical) logic, or from the motivations that logicians have offered for their technical pursuits. In settling on a list of subjects to classify as philosophy of logic, therefore, there is a certain degree of arbitrariness, since the issues which emerge from the technical development of logic can equally well be assigned to such areas as semantics, philosophy of language, philosophy of mathematics, epistemology, and even ethics (see SEMANTICS; LANGUAGE, PHILOSOPHY OF; MATHEMATICS, FOUNDATIONS OF).

1 The impact of modal logic

In the broad area of mathematical logic, the biggest philosophical punch is packed by modal logic, including tense logic (see MODAL LOGIC; TENSE AND TEMPORAL LOGIC). Modal logic has been important since Aristotle but has only been put on a rigorous footing in the second half of the twentieth century, by such figures as Hintikka, Kanger, Prior, and most especially Kripke (see SEMANTICS, POSSIBLE WORLDS). The most important philosophical outgrowth of this mathematical work is contained in Kripke's three lectures from January 1970 published as 'Naming and Necessity', in which Kripke draws out some ways in which possible worlds semantics is in tension with then-prevailing orthodoxies in the philosophy of language and mind. Some of Kripke's views have become new orthodoxies since (see ESSENTIALISM; PROPER NAMES; REFERENCE; for related work by David Lewis, Robert Stalnaker, David Kaplan and others that uses the possible worlds framework, see COUNTERFACTUAL CONDITIONALS; DEMONSTRATIVES AND INDEXICALS; DESCRIPTIONS).

To give some flavour of developments here, consider the familiar Fregean view that the relation of *reference* which holds between a name and its bearer is sustained by the relation of *presentation* which holds between the *sense* of the name and the bearer of the name: the name refers to such-and-such an object precisely because it expresses a sense which presents that object (see FREGE, G. §3; SENSE AND REFERENCE). When pressed for an explanation of what the senses of names are like, the natural Fregean response is to specify them, as Frege himself did in some cases, using definite descriptions (see DESCRIPTIONS). So, for instance, the sense of the name 'Aristotle' might be 'the pupil of Plato who taught Alexander'. However, though it may well in fact have been Aristotle who taught Alexander, there are many ways things might have gone (many 'possible worlds') in which someone other than Aristotle is taught by Plato and teaches Alexander: suppose Aristotle had got the appointment but been killed in an accident before he could take it up, and had been replaced at Philip's insistence by another pupil of Plato. The description 'the pupil of Plato who taught Alexander' is therefore 'non-rigid', in Kripke's terminology. That is, it can pick out different individuals in different possible worlds, and in some worlds may pick out no one (Philip for some reason comes to distrust Platonic pedagogy and fails to conduct an equal opportunity search). But it is clear from the formal semantics for modal logic that there is conceptual 'room' for a category of expression which is 'rigid', in the sense that it picks out the same object in every possible world, or at least in every possible world where it picks out any object at all. So the formal semantics prompts the question whether names in natural language behave as if their reference is determined by a sense which presents different individuals at different worlds, or whether they behave as if they are rigid designators. With a series of brilliant examples Kripke demonstrates that names are rigid designators and therefore do not express reference-determining senses which are non-rigid (see PROPER NAMES).

The idea that a formal semantics for a kind of logic provides an account of a possible semantics for a category of natural-language expression, opening the door to debate on whether it is the right account or not, also captures some of the philosophical bearing of kinds of logic other than modal logic. Thus free logic shows how name-like expressions can function without standard existential commitment; intuitionistic logic and many-valued logic show how a language can have a compositional semantics even if its sentences are not used to make statements with verification-transcendent truth-conditions which always either obtain or fail to obtain (see COMPOSITIONALITY; INTUITIONISTIC LOGIC AND ANTIREALISM; MANY-VALUED LOGICS, PHILOSOPHICAL ISSUES IN; PRESUPPOSITION). And second-order logic offers a particular way of understanding the semantic import of a range of puzzling locutions, such as plural quantifiers (see SECOND-ORDER LOGIC, PHILOSOPHICAL ISSUES IN). In all these cases the formal semantics for the logical system prompts debates about how well the semantics carries over to natural language.

2 Logic and language

There is also a collection of long-established topics discussion of which can be much improved, in rigour at least, in the light of the development of modern logic. For example, a distinction between propositions (or statements, or sentential contexts) which are *de dicto* and propositions (and so on) which are *de re* originates in medieval philosophy. But only contemporary modal logic affords the tools for a precise characterization of this distinction, although it must be granted that the distinction remains a puzzle in *epistemic* contexts (see DE RE/DE DICTO; DESCRIPTIONS). For other topics which can be classified in this way see ESSENTIALISM, EXISTENCE, IDENTITY, INDICATIVE CONDITIONALS, QUANTIFIERS and VAGUENESS. Again, to give some of the flavour of this kind of work, consider the *de re/de dicto* contrast. There is an evident syntactic difference between 'It is necessary that parents have children' and 'Parents are such that it is necessary that they have children', but just because there is a syntactic difference, it does not follow that there is any interesting difference in meaning. But the difference can be brought out quite precisely in possible worlds semantics. To say that it is necessary that parents have children is to say that in every possible world, the people who are parents *in that world* have children in that world; and this is an obvious truth. On the other hand, to say that parents are such that it is necessary that they have children is to say that the people who are parents *in the actual world* are such that they have children in every possible world. This is clearly false, even putting aside contingency of existence of actual parents. For given anyone who is actually a parent, there is a way things could have gone – a possible world – in which that person is childless, hence not a parent (see QUANTIFIERS, SUBSTITUTIONAL AND OBJECTUAL).

When a formal semantics for a system of logic is applied to a fragment of natural language, a very precise account of the literal content of sentences in that fragment is given. But there may be aspects of the meanings of those sentences which are omitted. Philosophical views may then divide over whether the formal semantics has been shown to be wanting as an account of the semantics of the fragment, or whether instead the aspects of meaning not captured have been shown not to belong to literal content (see PRESUPPOSITION). In the case of indicative conditionals, for instance, the formal semantics that is relevant is the simplest possible kind, namely, the truth-functional account of 'if … then …'. According to this account, 'If p then q' is true if p is false or if q is true, regardless of the actual meanings of p and q. So in particular, any indicative conditional with a true consequent is true; examples would include 'If lead floats in water then lead sinks in water' and 'If the solar system has nine planets then the Conservative Party lost the British elections in 1997'. Barring an astrological justification of the latter, both these conditionals look decidedly odd. But oddness is one thing, falsity another. The idea that such conditionals are false is based on the thought that if a conditional is true, then in establishing it in the most direct manner, non-redundant use has to be made of the antecedent. Spelling this out leads to relevance logic (see RELEVANCE LOGIC AND ENTAILMENT; INDICATIVE CONDITIONALS). On the other hand, if we say the conditionals are merely odd, we are led to some theory of communication to explain the oddness (see GRICE, H.P.; IMPLICATURE).

But we should not take away the impression that the traffic is all one way, from logic to language or from pure mathematics to pure philosophy. There is a two-way street here, with the above comments on conditionals representing a common phenomenon; that of a concern in the philosophy of language giving rise to a formal development which in turn feeds back into philosophy. For example, the idea that for a conditional to be true, the most direct way of establishing it must make non-redundant use of its antecedent seems clear enough on the face of it, but familiarity with logic of conditionals literature may well lead one to reconsider. This kind of dialectical interplay should continue to be a fruitful source of philosophical research for the foreseeable future.

LOGICAL ATOMISM

The name 'logical atomism' refers to a network of theses about the parts and structure of the world and the means by which language represents the world. Wittgenstein, in his *Tractatus Logico-Philosophicus*, expounds a version of logical atomism developed by him around the time of the First World War, as does Russell in works published contemporaneously. It is no accident that their work on logical atomism shares a common surface description since it resulted from their mutual influence at Cambridge. The common theme is that the meaning of our sentences is rooted in a primitive relation between simple expressions and their simple worldly bearers, the logical atoms. In a logically perfect language, atomic sentences describe configurations of these atoms, and complex sentences are combinations of the atomic sentences. But sentences of ordinary language may have a misleading surface form which is revealed as such by analysis. The common theme masks considerable differences of doctrine. In particular, there are differences in the nature of logical atoms and in the arguments for the existence of these atoms.

ALEX OLIVER

LOGICAL CONSTANTS

A fundamental problem in the philosophy of logic is to characterize the concepts of 'logical consequence' and 'logical truth' in such a way as to explain what is semantically, metaphysically or epistemologically distinctive about them. One traditionally says that a sentence *p* is a logical consequence of a set *S* of sentences in a language *L* if and only if (1) the truth of the sentences of *S* in *L* guarantees the truth of *p* and (2) this guarantee is due to the 'logical form' of the sentences of *S* and the sentence *p*. A sentence is said to be logically true if its truth is guaranteed by its logical form (for example, '2 is even or 2 is not even'). There are three problems presented by this picture: to explicate the notion of logical form or structure; to explain how the logical forms of sentences give rise to the fact that the truth of certain sentences guarantees the truth of others; and to explain what such a guarantee consists in.

The logical form of a sentence may be exhibited by replacing nonlogical expressions with a schematic letter. Two sentences have the same logical form when they can be mapped onto the same schema using this procedure ('2 is even or 2 is not even' and '3 is prime or 3 is not prime' have the same logical form: '*p* or not-*p*'). If a sentence is logically true then each sentence sharing its logical form is true. Any characterization of logical consequence, then, presupposes a conception of logical form, which in turn assumes a prior demarcation of the logical constants. Such a demarcation yields an answer to the first problem above; the goal is to generate the demarcation in such a way as to enable a solution of the remaining two.

Approaches to the characterization of logical constants and logical consequence are affected by developments in mathematical logic. One way of viewing logical constanthood is as a semantic property; a property that an expression possesses by virtue of the sort of contribution it makes to determining the truth conditions of sentences containing it. Another way is proof-theoretical: appealing to aspects of cognitive or operational role as the defining characteristics of logical expressions. Broadly, proof-theoretic accounts go naturally with the conception of logic as a theory of formal deductive inference; model-theoretic accounts complement a conception of logic as an instrument for the characterization of structure.

LOGICAL POSITIVISM

Introduction

Logical positivism (logical empiricism, neo-positivism) originated in Austria and Germany in the 1920s. Inspired by late nineteenth- and early twentieth-century revolutions in logic, mathematics and mathematical physics, it aimed to create a similarly revolutionary scientific philosophy purged of the endless controversies of traditional metaphysics. Its most important representatives were members of the Vienna Circle who gathered around Moritz Schlick at the University of Vienna (including Rudolf Carnap, Herbert Feigl, Kurt Gödel, Hans Hahn, Karl Menger, Otto Neurath and Friedrich Waismann) and those of the Society for Empirical Philosophy who gathered around Hans Reichenbach at the University of Berlin (including Walter Dubislav, Kurt Grelling and Carl Hempel). Although not officially members of either group, the Austrian philosophers Ludwig Wittgenstein and Karl Popper were, at least for a time, closely associated with logical positivism.

The logical positivist movement reached its apogee in Europe in the years 1928–34, but the rise of National Socialism in 1933 marked the effective end of this phase. Thereafter, however, many of its most important representatives emigrated to the USA. Here logical positivism found a receptive audience among such pragmatically, empirically and logically minded American philosophers as Charles Morris, Ernest Nagel and W.V. Quine. Thus transplanted to the English-speaking world of 'analytic' philosophy it exerted a tremendous influence – particularly in philosophy of science and the application of logical and mathematical techniques to philosophical problems more generally. This influence began to wane around 1960, with the rise of a pragmatic form of naturalism due to Quine and a historical-sociological approach to the philosophy of science due mainly to Thomas Kuhn. Both of these later trends, however, developed in explicit reaction to the philosophy of logical positivism and thereby attest to its enduring significance.

1 Historical background

Immanuel KANT, in the positivists' eyes, had made a lasting contribution to scientific philosophy – particularly in his rejection of the possibility of supersensible metaphysical knowledge and his reorientation of theoretical philosophy around the two questions 'how is pure mathematics possible?' and 'how is pure natural science possible?' In answering these questions Kant developed his famous defence of synthetic a priori knowledge – knowledge independent of sensible experience yet nonetheless substantively applicable to the empirical world. For Kant, the mathematical physics of Newton paradigmatically exemplified such synthetic a priori knowledge through its reliance on Euclidean geometry and fundamental laws of motion such as the law of inertia. Kant's theory of a priori faculties of the mind – the faculty of pure intuition or sensibility and the faculty of pure understanding – was then intended to explain the origin of synthetic a priori knowledge and thus make philosophically comprehensible the possibility of Newtonian mathematical physics.

After the intervening dominance of post-Kantian idealism, a number of German-speaking philosophers renewed the call for a scientific, epistemological and non-metaphysical form of philosophy. But these Neo-Kantian philosophers also had to face an important new challenge to the Kantian synthetic a priori: the nineteenth-century development of non-Euclidean geometry by Gauss, Bolyai, Lobachevskii, Riemann and Klein (see GEOMETRY, PHILOSOPHICAL ISSUES IN §§1, 3). Although some Neo-Kantians attempted to defend the uniqueness and apriority of Euclidean geometry nonetheless, others – especially those of the Marburg School such as Paul Natorp and Ernst Cassirer – aimed to generalize the synthetic a priori beyond its particular embodiment in classical Euclidean–Newtonian mathematical physics (see NEO-KANTIANISM). This latter tendency was similar in important respects to ideas the logical positivists were to elaborate.

But the most important nineteenth-century predecessors of logical positivism were Hermann von Helmholtz, Ernst MACH and Henri POINCARÉ. Through their efforts to comprehend the radical changes sweeping through nineteenth-century science, these three thinkers initiated a new style of scientific philosophy later taken up and systematized by the positivists. The changes in question included the rise of non-Euclidean geometry, the formulation of the conservation of energy and general thermodynamics, and the beginnings of scientific physiology and psychology. Helmholtz made fundamental contributions to all three areas. He based geometry on the postulate of 'free mobility' of rigid bodies, and, since all classical geometries of constant curvature – negative, positive or zero (Euclidean) – satisfy this postulate, he opposed the Kantian commitment to the aprioricity of geometry: whether space is Euclidean or non-Euclidean is an empirical question about the actual behaviour of rigid bodies. In physiology, Helmholtz articulated a general principle of psycho-physical correlation whereby our sensations correspond to – but are in no way pictures or images of – processes in the external physical world. These processes consist, in the end, of microscopic atoms interacting via central forces, and, on this basis, Helmholtz developed his famous interpretation of the conservation of energy.

Mach and Poincaré can be seen as reacting, in diverse ways, to Helmholtz. Mach attacked especially atomism and the idea of a psychophysical correlation between two incommensurable realms, and he advanced a programme for the unity of science based on immediately perceptible 'elements' or 'sensations'. The task of science consists solely in seeking correlations among such elements (as in phenomenological thermodynamics), and all dualistic and atomistic tendencies are to be purged as metaphysical via historico-critical analysis. This

Machian empiricism exerted a decisive influence on the logical positivists. Poincaré, on the other hand, influenced the positivists primarily through his philosophy of geometry. He agreed with Helmholtz's emphasis on the free mobility of rigid bodies but disagreed with Helmholtz's empiricism. According to Poincaré, the idea of a rigid body is an idealization that cannot be straightforwardly instantiated in the physical world. By freely choosing one of the three classical geometries as, so to speak, a definition of rigidity, we then first make it possible to carry out empirical investigations with real physical bodies. Physical geometry is thus neither synthetic a priori nor empirical: it is 'conventional' (see CONVENTIONALISM).

2 Relativistic physics

Albert Einstein's special (1905) and general (1916) theories of relativity entered this volatile intellectual situation as a revelation (see EINSTEIN, A.; RELATIVITY THEORY, PHILOSOPHICAL SIGNIFICANCE OF). And the relativistic revolution in physics directly stimulated SCHLICK, REICHENBACH and CARNAP to initiate a parallel revolution in scientific philosophy. All three thinkers agreed that relativity – especially through the general relativistic description of gravitation via a (four-dimensional) geometry of variable curvature – definitively refutes the Kantian idea that Euclidean geometry is synthetic a priori. Moreover, relativity arises from critical reflection on the empirical significance of spatiotemporal concepts in physics (in particular, the concept of simultaneity and the concept of motion) and thus demonstrates the fruitfulness of Mach's basic point of view. At the same time, however, through its use of sophisticated abstract mathematics, relativity also illustrates the limitations of Machian empiricism (according to which even mathematical concepts have an empirical origin). All three thinkers therefore attempted to formulate an intermediate position that would do justice to both Machian empiricism and the continued importance of a priori mathematical elements in physics. Poincaré's concept of convention came to play a central role.

Schlick, Reichenbach and Carnap first pursued rather different paths. Whereas Schlick emphasized from the outset that the Kantian synthetic a priori has no place at all in the new relativistic context, Reichenbach and Carnap initially attempted to salvage important aspects of Kantianism. Reichenbach began by distinguishing the idea of necessary and unrevisable truth from the idea of necessary presupposition of a given scientific conceptualization of nature. For Reichenbach, relativity refuted the former but embodied the latter. Kant was right that the necessary presuppositions of Newtonian physics included Euclidean geometry and the laws of motion. In moving to relativistic physics, however, these are replaced by fundamentally new presuppositions. We thus end up with a relativized version of the Kantian a priori (as constituting the presuppositions of a particular theory). Carnap, by contrast, began by distinguishing metrical from topological features of physical space. The latter are indeed synthetic a priori as Kant thought (they even depend on a kind of pure intuition), but the former – as general relativity has shown – essentially involve the behaviour of empirically given bodies. We thus end up with a weakening of the Kantian a priori (from metrical to topological features).

These early attempts to salvage aspects of the synthetic a priori did not survive, however. For Schlick's view that relativity is simply incompatible with Kant eventually won the day. Although the distinction between Poincaré's conventionalism and Helmholtzian empiricism was not entirely clear (and Reichenbach, in particular, preferred to associate his later viewpoint with Helmholtz rather than Poincaré), both Reichenbach and Carnap soon came to replace the Kantian notion of the a priori with Poincaré's concept of convention. Yet this form of conventionalism (unlike Poincaré's) was forged in the crucible of a revolutionary new physics and thus demonstrated the vitality and relevance of a new philosophy.

3 Logic and the foundations of mathematics

Whereas the positivists appealed to Poincaré's concept of convention (as realized, so they thought, in relativistic physics) to give a new answer to Kant's question concerning the possibility of pure natural science, they appealed to modern developments in logic and the foundations of mathematics to give a new answer to Kant's question concerning the possibility of pure mathematics. There were in fact two distinguishable sets of developments here. The formal point of view, typified by David Hilbert's logically rigorous axiomatization of geometry, freed geometry from any reference at all to intuitively spatial forms and instead portrayed its subject matter as consisting of any things whatever that satisfy the relevant axioms (see HILBERT'S PROGRAMME AND FORMALISM). Geometry is rigorously and a priori true, not because it reflects the structure of an intuitively given space, but rather because it 'implicitly defines' its subject matter via purely logical – but otherwise entirely undetermined – formulas. Mathematical truth, on this view, is identified with logical consistency. The 'logicism' of Gottlob Frege and Bertrand RUSSELL, by contrast, aimed to construct particular mathematical

disciplines (especially arithmetic) within an all-embracing system of logic. On this view mathematical disciplines (like arithmetic) indeed have a definite subject matter about which they express truths: namely, the subject matter of logic itself (propositions, classes, and so on). As thus purely logical, however, such pure mathematical disciplines express merely analytic truths and are not synthetic a priori (see LOGICISM).

Hilbert's formal point of view was pursued especially by Schlick, who in a sense made the notion of implicit definition, together with the associated distinction between undetermined form and determinate (given) content, the centrepiece of his philosophy. The logicist point of view, by contrast, was pursued especially by Carnap, who studied with Frege and then was decisively influenced by Russell. Indeed, Carnap was inspired by Russell's conception of 'logic as the essence of philosophy' to reconceive philosophy itself on the model of the logicist construction of arithmetic. He began, in *Der logische Aufbau der Welt* (1928), by developing a 'rational reconstruction' of empirical knowledge – an epistemology – within the logical framework of Russell and Whitehead's *Principia Mathematica* (1910–13). By defining or 'constituting' all concepts of empirical science within this logic from a basis of subjective 'elementary experiences', Carnap's reconstruction was to show, among other things, that the dichotomy between empirical truth and analytic/definitional truth is indeed exhaustive.

Yet the logic of *Principia Mathematica* was afflicted with serious technical difficulties: the need for special existential axioms such as the axioms of infinity and choice. Partly in response to such difficulties, Ludwig Wittgenstein asserted in his *Tractatus Logico-Philosophicus* that logic has no subject matter after all: the propositions of logic are entirely tautological or empty of content (see WITTGENSTEIN, L.J.J. §§3–7). Carnap eagerly embraced this idea, but he also attempted to adapt it to the new, post-*Principia* technical situation – which involved the articulation of the 'intuitionist' or 'constructivist' point of view by L.E.J. Brouwer and the development of meta-mathematics by Hilbert and Kurt Gödel (see INTUITIONISM; MATHEMATICS, FOUNDATIONS OF). In *Logische Syntax der Sprache* (1934) Carnap formulated his mature theory of formal languages and put forward his famous 'Principle of Tolerance' – according to which logic has no business at all looking for true or 'correct' principles. The task of logic is rather to investigate the structure of any and all formal languages – 'the boundless ocean of unlimited possibilities' – so as to map out and explore their infinitely diverse logical structures. Indeed, the construction and logical investigation of such formal languages became, for Carnap, the new task of philosophy. The concept of analyticity thereby took on an even more important role. For this concept characterizes logical as opposed to empirical investigation and thus now expresses the distinctive character of philosophy itself.

4 The Vienna Circle

Otto Neurath, Hans Hahn, and the physicist Philipp Frank initiated a discussion group in Vienna, beginning in 1907, in which they considered a combination of Machian empiricism with Poincaré's new insights into the conventional character of physical geometry. Deeply impressed by Schlick's work on relativity theory, they arranged (apparently with Einstein's help) to bring Schlick to the University of Vienna in 1922 to take over the Chair in Philosophy of the Inductive Sciences previously held by Mach. What we now know as the Vienna Circle quickly took shape. Reichenbach, who had become acquainted with Carnap through their common interest in relativity, introduced him to Schlick in 1924. In 1925 Carnap lectured to the Circle in Vienna on his new 'constitutional theory of experience' and became assistant professor under Schlick in 1926. The Circle then engaged in intensive discussions of Carnap's epistemology and Wittgenstein's *Tractatus*. Wittgenstein's view that all propositions are truth-functions of 'elementary propositions' was combined with Carnap's constitution of scientific concepts from a basis of 'elementary experiences' so as to create a new, logically rigorous form of empiricism according to which all meaningful – scientific – propositions are reducible to propositions about immediately given experience. And this was articulated as the 'official' philosophy of the Vienna Circle in the famous manifesto *Wissenschaftliche Weltauffassung* of 1929.

Neurath was the driving force in thus turning the Vienna Circle into a public philosophical movement. Trained in economics and the social sciences, Neurath was extremely active politically as a scientific neo-Marxist. In particular, he took the community of natural scientists as the model for a rationally organized human society, and, on this basis, he advocated a reorganization of both intellectual and social life from which all non-rational, 'metaphysical' elements would be definitively purged. In this sense, Neurath saw the philosophical work of the Vienna Circle as a reflection of the wider movement for a *neue Sachlichkeit* then current in Weimar culture – as typified, for example, by the Dessau Bauhaus. As in the wider culture, this movement stood in philosophy for a rejection of individualism in favour of the cooperative, piecemeal, and

'technological' approach to problems exemplified in the sciences, and it was therefore particularly hostile to what was perceived as a return to the metaphysical system-building of post-Kantian idealism by influential German philosophers such as Martin Heidegger. Carnap was especially sympathetic to Neurath's broader philosophical-political vision and clearly expresses this vision in the Preface to the *Aufbau*. Schlick, by contrast, preferred a more individualistic model of philosophy and resisted the idea of a 'movement'.

This divergence between a 'left wing' and a 'right wing' of the Circle emerged in the sphere of epistemology in a debate over 'protocol-sentences' in the years 1930–4. At issue was the status of the basic propositions or protocols in which the results of scientific observation are recorded. It had initially appeared, in Carnap's constitutional system of the *Aufbau*, that such propositions must express private, subjective sense-experience. For Neurath, however, this view was inconsistent with the publicity and intersubjectivity required by science. He therefore advocated a more naturalistic conception of protocols as sentences accepted by the scientific community as recording the results of observation at a given time. These sentences must thus be expressible within the public and 'physicalistic' language of unified science and hence, like all other sentences, are in principle revisable. Schlick was deeply shocked by Neurath's view – which he took to represent an abandonment of empiricism in favour of the coherence theory of truth (see TRUTH, COHERENCE, THEORY OF). Carnap attempted, in typical fashion, to mediate the dispute: at issue was simply a choice between two different languages in which to formulate or rationally reconstruct the results of unified science. Although Neurath's thoroughly intersubjective 'physicalistic' language (where, as Karl POPPER emphasized especially, every sentence is revisable) was clearly preferable on pragmatic grounds, Carnap held that this choice – like every other choice of formal language – is in the end conventional. Empiricism, in Carnap's hands, is itself framed by conventional and hence non-empirical choices (see VIENNA CIRCLE).

5 Emigration, influence, aftermath

The rise of the Nazi regime set off a wholesale migration of logical positivists to the English-speaking world. Carnap, who had become professor at Prague in 1931, moved in 1936 to the University of Chicago. Reichenbach, who had fled to Istanbul in 1933, moved in 1938 to the University of California at Los Angeles. (After Reichenbach's death in 1953 Carnap took over his position at UCLA, beginning in 1954.) Neurath, after leaving Vienna for The Hague in 1934, fled to England in 1940 – where he worked in Oxford until his death in 1945. Friedrich Waismann fled for England as well, where he lectured at Oxford from 1939. Philip Frank emigrated to the USA (also from Prague) in 1938 and settled at Harvard in 1939. Karl Menger took up a position at Notre Dame in 1937, and Kurt Gödel became a member of the Institute for Advanced Study at Princeton in 1940. Herbert Feigl went first to the University of Iowa in 1933 and then to the University of Minnesota in 1940, where he founded the influential Minnesota Center for the Philosophy of Science in 1953. Carl Hempel joined Carnap at the University of Chicago in 1939 and, after teaching at Queens College and Yale, settled at Princeton in 1955. (Schlick was murdered by a deranged student at the University of Vienna in 1936.)

The growth of philosophy of science in the USA was decisively shaped by the work of Carnap, Reichenbach and Hempel. Reichenbach influenced especially the development of philosophy of physics through his work on geometry, relativity and the direction of time (see RELATIVITY THEORY, PHILOSOPHICAL SIGNIFICANCE OF). Hempel published extraordinarily influential papers on the logical analysis of explanation and confirmation and thereby furthered the ideal of scientific philosophy first articulated by Carnap (see EXPLANATION; CONFIRMATION THEORY). Carnap himself continued the construction of formal languages in which such concepts as testability, modality and probability could be rationally reconstructed or 'explicated' and thus contributed further to the same ideal. Indeed, Carnap's explication of concepts through the construction of formal languages influenced the English-speaking world of analytic philosophy far beyond the borders of philosophy of science. Developments in formal semantics and philosophy of language, in particular, rested on Carnap's initial work on modality (see SEMANTICS).

The Carnapian ideal of explication is based on a sharp distinction between logical and empirical investigation, analytic and synthetic truth. In his *Logical Syntax of Language* (1934) Carnap had attempted a general explication of the concept of analyticity itself – a general formal method for distinguishing, within the context of any given formal language, the analytic from the synthetic sentences of that language. After accepting Alfred Tarski's semantical conception of truth in 1935, however, Carnap abandoned the approach of *Logical Syntax* and frankly admitted that (although explications for various particular languages could still be constructed) he now had no generally applicable explication of the concept of analyticity. After studying with Carnap in the early 1930s, W.V.

Quine then exploited this situation to attack the concept of analyticity as such and, on this basis, to attack the Carnapian ideal of logical explication as well (see QUINE, W.V. §§2, 4). Philosophy, for Quine, is itself a kind of empirical science – a branch of human psychology or 'naturalized epistemology' (see NATURALIZED EPISTEMOLOGY). Moreover, at the same time that Quine was articulating this new philosophical vision, Thomas KUHN published *The Structure of Scientific Revolutions* (1962) in the *International Encyclopedia of Unified Science* edited by Carnap and Charles Morris. Whereas Carnap had relegated the (conventional) choice of scientific language to the limbo of pragmatics, Kuhn concentrated on those factors – especially social factors – which, in a scientific revolution, determine precisely this kind of choice. These ideas, in harmony with Quine's more general naturalistic point of view, then led to historical and sociological approaches to the study of science and thus, in the end, to the decline of logical analyses of scientific language in the Carnapian style.

LOGICISM

The term 'logicism' refers to the doctrine that mathematics is a part of (deductive) logic. It is often said that Gottlob Frege and Bertrand Russell were the first proponents of such a view; this is inaccurate, in that Frege did not make such a claim for all of mathematics. On the other hand, Richard Dedekind deserves to be mentioned among those who first expressed the conviction that *arithmetic* is a branch of logic.

The logicist claim has two parts: that our knowledge of mathematical theorems is grounded fully in logical demonstrations from basic truths of logic; and that the concepts involved in such theorems, and the objects whose existence they imply, are of a purely logical nature. Thus Frege maintained that arithmetic requires no assumptions besides those of logic; that the concept of number is a concept of pure logic; and that numbers themselves are, as he put it, logical objects.

This view of mathematics would not have been possible without a profound transformation of logic that occurred in the late nineteenth century – most especially through the work of Frege. Before that time, actual mathematical reasoning could not be carried out under the recognized logical forms of argument: this circumstance lent considerable plausibility to Immanuel Kant's teaching that mathematical reasoning is not 'purely discursive', but relies upon 'constructions' grounded in intuition. The new logic, however, made it possible to represent standard mathematical reasoning in the form of purely logical derivations – as Frege, on the one hand, and Russell, in collaboration with Whitehead, on the other, undertook to show in detail.

It is now generally held that logicism has been undermined by two developments: first, the discovery that the principles assumed in Frege's major work are inconsistent, and the more or less unsatisfying character (or so it is claimed) of the systems devised to remedy this defect; second, the epoch-making discovery by Kurt Gödel that the 'logic' that would be required for derivability of *all* mathematical truths can in principle not be 'formalized'. Whether these considerations 'refute' logicism will be considered further below.

LOGOS

The noun *logos* derives from the Greek verb *legein*, meaning 'to say' something significant. *Logos* developed a wide variety of senses, including 'description', 'theory' (sometimes as opposed to 'fact'), 'explanation', 'reason', 'reasoning power', 'principle', 'ratio' and 'prose'.

Logos emerges as a philosophical term with Heraclitus (*c.*540–*c.*480 BC), for whom it provided the link between rational discourse and the world's rational structure. It was freely used by Plato and Aristotle and especially by the Stoics, who interpreted the rational world order as immanent deity. Platonist philosophers gave pre-eminence to *nous*, the intuitive intellect expressed in *logos*. To Philo of Alexandria and subsequently to Christian theologians it meant 'the Word', a derivative divine power, at first seen as subordinate but eventually coordinated with the Father.

CHRISTOPHER STEAD

LOKAYATA

See MATERIALISM, INDIAN SCHOOL OF

LOMBARD, PETER (1095/1100–60)

Peter Lombard's philosophical views are important given the formative role his *Sententiae in IV libris distinctae* (Four Books of Sentences) played in the education of university theologians in the high Middle Ages, many of whom were also philosophers. Lombard staunchly opposes theologies, cosmologies and anthropologies of a Platonic or Neoplatonic type. While conversant with new trends in logic in his day, he is disinclined to treat theological issues as illustrations of the rules of formal logic or natural philosophy, preferring to view them from a metaphysical perspective. In his doctrine of God he deliberately eschews terminology associated with any one philosophical school. In his anthropology and sacramental theology he shows a marked preference for Aristotelianism. The hospitability of his theology to Aristotelianism and to a philosophical treatment of a range of theological questions made his *Sentences* elastic enough to accommodate the reception of Greco-Arabic thought and to serve as a pedagogical framework usable by philosophers of every persuasion during the succeeding three centuries.

LOTTERY PARADOX

See PARADOXES, EPISTEMIC

LOTZE, RUDOLPH HERMANN (1817–81)

Lotze was among the pre-eminent figures in German academic philosophy between the demise of Absolute Idealism and the rise of Neo-Kantianism proper. He sought to avoid two extremes: first, that of an idealism which seeks to deduce the world from a single, general principle; and, second, that of a realism which, by divorcing reality from the mind, splits the world into two utterly separate spheres. The search for knowledge should be tempered by a recognition of the results of natural science and sobered by the awareness that reality will, by necessity, always outstrip thought. Furthermore, our mental life cannot be reduced to purely intellectual functions: feelings and evaluations, for example, are also an integral part of human existence. While there can be no a priori deduction of a metaphysical system, a teleological interpretation, which elucidates the ultimate value of man and the world, must supplement purely naturalistic explanation. The universe has the significance of an unfolding plan, where things are subject to the general laws of order, expressing spiritual import. In this way, Lotze combined a kind of respect for the findings of scientific research with his own peculiar idealistic programme.

DAVID SULLIVAN

LOVE

Love is usually understood to be a powerful emotion involving an intense attachment to an object and a high evaluation of it. On some understandings, however, love does not involve emotion at all, but only an active interest in the wellbeing of the object. On other accounts, love is essentially a relationship involving mutuality and reciprocity, rather than an emotion. Moreover, there are many varieties of love, including erotic/romantic love, friendly love, and love of humanity. Different cultures also recognize different types of love. Love has, as well, a complicated archaeology: because it has strong links with early experiences of attachment, it can exist in the personality at different levels of depth and articulateness, posing special problems for self-knowledge. It is mistake to try to give too unified an account of such a complex set of phenomena.

Love has been understood by many philosophers to be a source of great richness and energy in human life. But even those who praise its contribution have seen it as a potential threat to virtuous living. Philosophers in the Western tradition have therefore been preoccupied with proposing accounts of the reform or 'ascent' of love, in order to demonstrate that there are ways of retaining the energy and beauty of this passion while removing its bad consequences.

MARTHA C. NUSSBAUM

LÖWENHEIM–SKOLEM THEOREMS AND NONSTANDARD MODELS

Sometimes we specify a structure by giving a description and counting anything that satisfies the description as just another model of it. But at other times we start from a conception we try to articulate, and then our articulation may fail to pin down what we had in mind. Sets seem to have had such a fate. For millennia sets lay fallow in logic, but when cultivated by mathematics in the nineteenth century, they seemed to bear both a foundation and a theory of the infinite. The paradoxes of set theory seemed to threaten this promise. With an eye to proving freedom from paradox, versions of set theory were articulated rigorously. But around 1920, Löwenheim and Skolem proved that no such formalized set theory can come out true only in the hugely infinite world it seemed to reveal, for if it is true in such a world, it will also be true in a world of the smallest infinite size. (Versions of this remain true even if we augment the standard expressive devices used to formalize set theory.) But then, Skolem inferred, we cannot articulate sets determinately enough for them to constitute a firm foundation for mathematics.

W.D. HART

LUCRETIUS (*c*.94–*c*.55 BC)

Titus Lucretius Carus was a Roman Epicurean philosopher and poet. About his life and personality little can be said with certainty, yet his only known work, *On the Nature of Things* (*De rerum natura*), is of considerable size and one of the most brilliant achievements of Latin poetry. A didactic poem in six books, it expounds Epicurean physics. Its manifesto is to abolish the fear of gods and of death by demonstrating that the soul is mortal and the world not governed by gods but by mechanical laws.

MICHAEL ERLER

LUKÁCS, GEORG (1885–1971)

Lukács' *Geschichte und Klassenbewusstsein* (History and Class Consciousness) (1923) is, for both its intrinsic merits and its enormous influence, the most important work of Marxist philosophy to have appeared in the twentieth century. It sought to render explicit the dependence of Marx's thought on Hegel's dialectic as a means of elucidating both the distinctive character of historical materialism as a form of theoretical inquiry and its revolutionary rejection of the modes of thinking prevailing in capitalist society. Lukács' general aim had been shared by the authors of the first philosophical reflections on Marx's project – Engels and Plekhanov, for example, had stressed its debt to Hegel. Lukács, however, sought to draw Marx into that broad current of twentieth-century Continental thought which has drawn a sharp distinction between the methods of the physical sciences, suitable at best for analysing inanimate nature, and those of the human sciences, whose aim is to interpret human actions in the light of the thoughts which move them. Thus Lukács sees Marx as the theorist, not of the laws of the dialectic or of inevitable social transformation, but of revolutionary subjectivity, of the proletariat as 'the identical subject–object' of history. This was a version of Marxism which suited the times, in the immediate aftermath of the Russian Revolution of October 1917. As the revolutionary tides receded, Lukács found philosophical and political reasons for retreating to a more orthodox historical materialism which laid much greater stress on objective constraints and processes than his version of the early 1920s had. Yet the force of its overall argument and the quality of its individual analyses have made *History and Class Consciousness* a constant reference-point in subsequent discussions of Marxist theory.

ALEX CALLINICOS

ŁUKASIEWICZ, JAN (1878–1956)

Before 1918, Łukasiewicz's interests centred on logic (in the broad sense) and philosophy, and he worked on induction and probability. He also wrote an important historical book on the principle of contradiction in Aristotle. After 1918, Łukasiewicz concentrated almost entirely on mathematical logic and was the main organizer of the Warsaw School of Logic. The discovery of many-valued systems of logic is perhaps the most important result he achieved. He also invented an ingenious logical symbolism in which brackets (or other punctuation signs) are not necessary (bracket-free or Polish notation). Propositional calculi became a favourite topic of Łukasiewicz's logical investigations. The history of logic was another subject in which Łukasiewicz achieved important results.

LUTHER, MARTIN (1483–1546)

Martin Luther was an Augustinian monk who found the theology and penitential practices of his times inadequate for overcoming fears about his

salvation. He turned first to a theology of humility, whereby confession of one's own utter sinfulness is all that God asks, and then to a theology of justification by faith, in which human beings are seen as incapable of any turning towards God by their own efforts. Without preparation on the part of sinners, God turns to them and destroys their trust in themselves, producing within them trust in his promises made manifest in Jesus Christ. Regarding them in unity with Christ, God treats them as if they had Christ's righteousness: he 'justifies' them. Faith is produced in the sinner by the Word of God concerning Jesus Christ in the Bible, and by the work of the Holy Spirit internally showing the sinner the true subject matter of the Bible. It is not shaped by philosophy, since faith's perspective transcends and overcomes natural reason. Faith, through the working of God's Holy Spirit within the believer, naturally produces good works, but justification is not dependent upon them – they are free expressions of faith in love. Nevertheless, secular government with its laws and coercion is still necessary in this world because there are so few true Christians. Luther's theology brought him into conflict with the Church hierarchy and was instrumental in the instigation of the Reformation, in which the Protestant churches split from Rome.

LYOTARD, JEAN-FRANÇOIS (1924–98)

Jean-François Lyotard was a prominent French philosopher who is generally considered the leading theorist of postmodernism. His work constitutes an insistent critique of philosophical closure, historical totalization and political dogmatism and a re-evaluation of the nature of ethics, aesthetics and politics after the demise of totalizing metatheories.

In his early works, Lyotard confronts the limitations of dialectical philosophy and structuralist linguistics and analyses the disruptive, extradiscursive force of desire and the nonrepresentational or figurative dimensions of art and literature. In *La Condition postmoderne* (1979) (*The Postmodern Condition*, 1984), he treats narrative pragmatics and language games as the bases for a critical approach to postmodern art and politics, as well as to the problem of justice. Recent texts insist on the obligation of philosophy, politics and writing to bear witness to heterogeneity and to what is repressed or forgotten in all representations of the past. His work questions the limits of philosophy, aesthetics and political theory in terms of problems linked to the irreducible complexities of art and literature and the nonrepresentational affects of historical-political events.

DAVID CARROLL

M

MACH, ERNST (1838–1916)

Mach was an Austrian physicist and philosopher. Though not one of the great philosophers, he was tremendously influential in the development of 'scientific philosophy' in the late nineteenth and early twentieth centuries. A vigorous opponent of 'metaphysics', he was celebrated as a progenitor of logical positivism. His work is regarded as a limiting case of pure empiricism; he stands between the empiricism of Hume and J.S. Mill, and that of the Vienna Circle.

Mach's positivist conception of science saw its aims as descriptive and predictive; explanation is downgraded. Scientific laws and theories are economical means of describing phenomena. Theories that refer to unobservable entities – including atomic theory – may impede inquiry. They should be eliminated where possible in favour of theories involving 'direct descriptions' of phenomena. Mach claimed to be a scientist, not a philosopher, but the 'Machian philosophy' was 'neutral monism'. Close to phenomenalism, it saw the world as functionally related complexes of sensations, and aspired to anti-metaphysical neutrality.

ANDY HAMILTON

MACHIAVELLI, NICCOLÒ (1469–1527)

Florentine diplomat, dramatist and political thinker, Machiavelli's treatise, *Il principe* (The Prince) (1532), has earned him notoriety as a political immoralist (or at least an amoralist) and a teacher of evil. In *The Prince*, Machiavelli posits a complex relationship between ethics and politics that associates princely *virtù* with the capacity to know and act within the political world as it 'is', and with the beastly abilities to dispense violence and practise deception. Behind this argument dwells the distinctly Machiavellian insight that politics is a realm of appearances where the practice of moral or Christian virtues often results in a prince's ruin, while knowing 'how not to be good' may result in greater security and wellbeing for both prince and people. Machiavelli warns that the prince's possibilities for success in this matter are always mediated by fortune; hence the prudent prince is one who is prepared to resist fortune by adapting his procedure to the times and his nature to 'the necessity of the case'.

A less notorious but equally influential text is the *Discorsi sopra la prima deca di Tito Livio* (Discourses on the First Ten Books of Titus Livy) (1531), in which Machiavelli offers a defence of popular liberty and republican government that takes the ancient republic of Rome as its model and emphasizes the role of the people in the 'public administration' of the city. However, Machiavelli also argues that a republic is only as successful in self-governance as its citizens are infused with civic *virtù* and therefore not corrupted. Accordingly, he praises the work of political founders who craft republican laws and institutions, and religious founders who fuse God and *patria* as one in the people's hearts. The apparent tension between Machiavelli's republican sympathies in *Discourses* and his elitist proclivities in *The Prince* has helped to fuel a vast interpretive literature concerning his political attitudes, his theory of politics, and the nature and meaning of 'machiavellianism' in Western political thought.

MARY G. DIETZ

MACINTYRE, ALASDAIR (1929–)

Alasdair MacIntyre has contributed to the diverse fields of social, moral and political philosophy. He is one of the leading proponents of a virtue ethical approach in moral philosophy, part of a wider attempt to recover an Aristotelian conception of both morality and politics. His return to ancient sources has been powered by a critical indictment of the modern moral predicament, which MacIntyre regards as theoretically confused and practically fragmented; only a return to a tradition which

synthesizes Aristotelian and Augustinian themes will restore rationality and intelligibility to contemporary moral and political life.

ALAN THOMAS

MCTAGGART, JOHN MCTAGGART ELLIS (1866–1925)

McTaggart was one of the last of the 'British Idealists', the group of British philosophers, such as B. Bosanquet and F.H. Bradley, who took their inspiration from Hegel. In his early writings from the 1890s, McTaggart gave a critical exposition of themes from Hegel's logic before advancing his own distinctive idealist positions concerning time, the mind, and reality in general. But in his writings from 1910 he developed an independent account of the structure of existence from which he then argued for the same idealist positions as before.

The thesis for which McTaggart is now most famous is that of the unreality of time; what is even more difficult to come to terms with is his thesis that the ultimate reality of the world comprises a community of selves wholly constituted by their loving perceptions of each other. This thesis is a manifestation of a mysticism that is an essential element in McTaggart's philosophy; yet this mysticism is combined with a rationalist determination, reminiscent of Spinoza, to vindicate mystical insights by the light of pure reason alone.

THOMAS BALDWIN

MAGIC

Magic is the art of influencing the workings of nature through occult powers. It can be found in most societies throughout history. It is often defined by contrast with other subjects, such as science, rationality and religion. Practitioners of magic might fashion themselves as necromancers, magi or natural philosophers; and accused practitioners were often labelled as sorcerers, heretics or witches. Concentrated, though at times incoherent, expositions of what we might call the epistemology of magic reached their height in European philosophy in late antiquity in the writings of Plotinus, Porphyry and Proclus; this interest was rekindled in the Renaissance in the writings of Agrippa, Pico, Ficino and others in what is often described as the Hermetic or Occultist tradition. Whether magic worked according to natural, demonic or divine forces was debated, and during the Renaissance demonology shifted from a theological to a natural philosophical pursuit. In the Middle Ages explaining how magic worked was a concern of theologians; in the Renaissance it was a concern of natural philosophers and physicians; and in the modern period it is a concern of anthropologists and historians. Magic has always been associated with trickery and danger, and with knowledge and power.

MAIMON, MOSES BEN

See Maimonides, Moses

MAIMONIDES, MOSES (1138–1204)

Called the Rambam in the Hebrew sources, an acronym on his name, and known in Islamic texts as Musa ibn Maimun, Rabbi Moses ben Maimon is best known in the West as Moses Maimonides and is generally recognized as the greatest of the medieval Jewish philosophers. Maimonides lived his mature life in Egypt and earned his living as a physician. He was the author of ten medical works but gained fame in his own lifetime for his work on Jewish law (*halakhah*), chiefly the *Kitab al-Fara'id* (*Sefer ha-Mitzvot*, that is, the Book of the Commandments), cataloguing the traditional 613 commandments of the Pentateuch; *Kitab al-Siraj* (*Sefer ha-Maor, Perush ha-Mishnah*, Commentary on the Mishnah); and, above all, the *Mishneh Torah* (The Law in Review), a comprehensive and still authoritative code of rabbinic law. The clarity and definitiveness of the Mishneh Torah led to its criticism and (after Maimonides' death) even condemnation by some rabbis, who prized the ongoing dialectic of Talmudic disputation and felt suspicious of Maimonides' rationalism.

Maimonides' philosophic masterpiece, the *Dalalat al-Ha'irin* or *Guide to the Perplexed*, was written in Arabic, with a view to helping the more intellectually inquisitive readers of the Torah, who were troubled by the apparent disparity between biblical and scientific/philosophical ideas. The work frames a powerful but not supercilious rationalism that locates and accommodates many biblical postulates and profits from the instruction of the rabbinic (Talmudic) sources and from critical appropriation of the achievements of Muslim philosophers and theologians and their Greek predecessors. It defends the doctrine of the world's creation against the eternalism of Neoplatonic Aristotelians but rejects the notion that creation (or eternity) is subject to proof. Rather, Maimonides argues, creation is

preferable to its alternative, and more plausible, because it preserves the idea of divine volition as an explanation for the emergence of complexity from divine simplicity, and because it marks the difference God's act made to the existence and nature of the world.

God is pure perfection and absolute simplicity. The Torah's anthropomorphisms themselves lead us to that realization, if we follow the dialectic by which prophetic language directs us to ever higher conceptions of divine transcendence. Biblical poetry and the concrete demands of the Law are accommodations to our creaturely limitations. Such accommodations are made possible by the material side of the prophet's nature, as manifested in language and imagination, which are, no less than intellect, expressions of God. For matter in general is an expression of God, apprehensible to us through what seems wilful or arbitrary in nature. It is not a positive principle or hypostasis, but it is a necessary concomitant of the act of creation itself. For without it nothing other than God would exist. Our task as humans is to discipline our material natures – not to battle or seek to destroy them but to put them to work in behalf of our self-perfection, through which our inner, intellectual affinity to God will be realized.

Maimonides' synthetic approach, accommodating to one another the insights of reason and the teachings of Scripture and tradition, was highly valued by Aquinas, who frequently cites him, and by other European philosophers such as Jean Bodin. Leibniz warmly appreciated Maimonides' thought, as his reading notes reveal. Among subsequent Jewish thinkers, Maimonides' work became the paradigm of Jewish rationalism for his admirers and detractors alike. His philosophy was at the core of the philosophic tradition that Spinoza addressed. Even today practitioners of Jewish philosophy stake out their positions in reference to Maimonides and formulate their own views as appropriations, variants or interpretations of the elements of his thought.

MAISTRE, JOSEPH DE (1753–1821)

Count Joseph de Maistre was a major theorist of the Counter-Enlightenment, whose writings inspired generations of French Catholic royalists and stimulated thinkers diverse as Saint- Simon, Auguste Comte and Charles Maurras. He is known especially for his providential interpretation of the French Revolution, his support for a Bourbon Restoration in France, his opposition to all contractual theories of government, his arguments in favour of papal infallibility, his philosophical speculations on violence and bloodshed, his critique of John Locke's epistemology and his attack on Francis Bacon's 'scientism'.

RICHARD A. LEBRUN

MALEBRANCHE, NICOLAS (1638–1715)

Nicolas Malebranche, a French Catholic theologian, was the most important Cartesian philosopher of the second half of the seventeenth century. His philosophical system was a grand synthesis of the thought of his two intellectual mentors: Augustine and Descartes. His most important work, *De la recherche de la vérité* (The Search After Truth), is a wide-ranging opus that covers various topics in metaphysics, epistemology, ethics, physics, the physiology of cognition, and philosophical theology. It was both admired and criticized by many of the most celebrated thinkers of the period (including Leibniz, Arnauld and Locke), and was the focus of several fierce and time-consuming public debates. Malebranche's philosophical reputation rests mainly on three doctrines. Occasionalism – of which he is the most systematic and famous exponent – is a theory of causation according to which God is the only genuine causal agent in the universe; all physical and mental events in nature are merely 'occasions' for God to exercise his necessarily efficacious power. In the doctrine known as 'vision in God', Malebranche argues that the representational ideas that function in human knowledge and perception are, in fact, the ideas in God's understanding, the eternal archetypes or essences of things. And in his theodicy, Malebranche justifies God's ways and explains the existence of evil and sin in the world by appealing to the simplicity and universality of the laws of nature and grace that God has established and is compelled to follow. In all three doctrines, Malebranche's overwhelming concern is to demonstrate the essential and active role of God in every aspect – material, cognitive and moral – of the universe.

STEVEN NADLER

MANDEVILLE, BERNARD (1670–1733)

Bernard Mandeville's *Fable of the Bees* (1714) scandalized contemporaries by arguing that the flourishing commercial society they valued depended on vices they denounced. It resulted not only from the complementary satisfaction of appetites but was also based upon pride, envy and

shame, which Mandeville traced to 'self-liking'. Numerous individuals, driven by their own desires, acted independently to produce goods which required extensive, cooperative operations – an idea central to the economic concept of a market.

Mandeville initially appeared to credit 'skilful politicians' with originating morality and society. However, in defending and expounding his views, he set out 'conjectural histories' of the gradual development of many complex social activities and institutions, including language and society itself, thereby denying that they had been invented by public spirited heroes. Throughout his works, Mandeville adopted a strict criterion of virtue, repeatedly denying that he was advocating, rather than exposing, the vices he identified as inherent in human society.

M.M. GOLDSMITH

MANICHEISM

Manicheism is a defunct religion, born in Mesopotamia in the third century AD and last attested in the sixteenth century in China. Its founder, Mani (*c.*216–76), had some familiarity with Judaism, Christianity, Zoroastrianism and Buddhism, and aimed to supplant them all. He taught a form of dualism, influenced by earlier Gnostics: God is opposed by forces of darkness; they, not God, created human beings, who nevertheless contain particles of light which can be released by abstemious living. Two points of contrast with Catholic Christianity are particularly striking. First, in Manicheism, sinfulness is the natural state of human beings (because of their creators), and does not stem from Adam's Fall. Second, the Manichean God did not create and does not control the forces of darkness (although he will eventually triumph); hence the problem of evil does not arise in as stark a form as it does for the all-powerful Christian God.

Although Mani's own missionary journeys took him eastwards, it was in the Roman Empire to the west that the main impact of his teaching was first felt; Augustine of Hippo was an adherent for nine years. The religion was eventually suppressed in the Roman Empire, and driven east by the Arab conquest of Mesopotamia. In the West, various Christian heresies were loosely called Manichean throughout the Middle Ages.

MANY-VALUED LOGICS

Many-valued logics may be distinguished from classical logic on purely semantic grounds. One of the simplifying assumptions on which classical logic is based is the thesis of bivalence, which states that there are only two truth-values – true and false – and every sentence must be one or the other. Many-valued logics reject the thesis of bivalence and permit more than two truth-values.

CHARLES G. MORGAN

MANY-VALUED LOGICS, PHILOSOPHICAL ISSUES IN

The first philosophically-motivated use of many-valued truth tables arose with Jan Łukasiewicz in the 1920s. What exercised Łukasiewicz was a worry that the principle of bivalence, 'every statement is either true or false', involves an undesirable commitment to fatalism. Should not statements about the future whose eventual truth or falsity depends on the actions of free agents be given some third status – 'indeterminate', say – as opposed to being (now) regarded as determinately true or determinately false? To implement this idea in the context of the language of sentential logic (with conjunction, disjunction, implication and negation), we need to show – if the usual style of treatment of such connectives in a bivalent setting is to be followed – how the status of a compound formula is determined by the status of its components.

Łukasiewicz's decision as to how the appropriate three-valued truth-functions should look is recorded in truth tables in which (determinate) truth and falsity are represented by '1' and '3' respectively, with '2' for indeterminacy. Consider the formula $A \vee B$ ('A or B'), for example, when A has the value 2 and B has the value 1. The value of $A \vee B$ is 1, reasonably enough, since if A's eventual truth or falsity depends on how people freely act, but B is determinately true already, then $A \vee B$ is already true independently of such free action. There are no constraints as to which values may be assigned to propositional variables. The law of excluded middle is invalidated in the case of indeterminacy: if p is assigned the value 2, then $p \vee \neg p$ also has the value 2. This reflects Łukasiewicz's idea that such disjunctions as 'Either I shall die in a plane crash on January 1, 2030 or I shall not die in a plane crash on January 1, 2030' should not be counted as logical truths, on pain of incurring the fatalistic commitments already alluded to.

Together with the choice of designated elements (which play the role in determining validity played by truth in the bivalent setting), Łukasiewicz's tables constitute a (logical) matrix. An alternative three-element matrix, the 1-Kleene matrix, involves putting $2 \rightarrow 2 = 2$, leaving everything else unchanged.

And a third such matrix, the 1,2-Kleene matrix, differs from this in taking as designated the set of values $\{1, 2\}$ rather than $\{1\}$. The 1-Kleene matrix has been proposed for the semantics of vagueness. In the case of a sentence applying a vague predicate, such as 'young', to an individual, the idea is that if the individual is a borderline case of the predicate (not definitely young, and not definitely not young, to use our example) then the value 2 is appropriate, while 1 and 3 are reserved for definite truths and falsehoods, respectively. Łukasiewicz also explored, as a technical curiosity, *n*-valued tables constructed on the same model, for higher values of *n*, as well as certain infinitely many-valued tables. Variations on this theme have included acknowledging as many values as there are real numbers, with similar applications to vagueness and approximation in mind.

LLOYD HUMBERSTONE

MARCUSE, HERBERT (1898–1979)

Herbert Marcuse endured a brief moment of notoriety in the 1960s, when his best-known book, *One-Dimensional Man* (1964), was taken up by the mass media as the Bible of the student revolts which shook most Western countries in that decade. Though Marcuse's actual political influence was uneven, his public image was not wholly misleading. On the one hand, he popularized the critique of post-war capitalism that he, with the other theorists of the Frankfurt School, had helped develop: the Western liberal democracies were, they argued, 'totally administered societies' permeated by the values of consumerism, in which the manufacture and satisfaction of 'false needs' served to prevent the working class from gaining any genuine insight into their situation. On the other hand, Marcuse never fully subscribed to the highly pessimistic version of Marxism developed by the central figures of the Frankfurt School, Adorno and Horkheimer. He hoped that revolts by an underclass of 'the outcasts and the outsiders, the exploited and persecuted of other races and other colours, the unemployed and unemployable' would stimulate a broader social transformation. Underlying this affirmation of revolutionary possibilities was a conception of Being as a state of rest in which all conflicts are overcome, where rational thought and sensual gratification are no longer at war with one another, and work merges into play. Intimations of this condition – which could only be fully realized after the overthrow of capitalism (and perhaps not even then) – were, Marcuse believed, offered in art, 'the possible Form of a free society'. Imagination could thus show politics the way.

ALEX CALLINICOS

MARGINALITY

Traditional definitions of marginal persons include those who live in two worlds, but do not feel well integrated into either, and those who live in societies which are in the process of being assimilated and incorporated into an emerging global society. The influence of Anglo-American and European cultures has brought this situation into existence. A broader, more contemporary understanding of marginality is the condition of feeling marginal in relation to various concepts of the centre. This state produces a stigmatized identity, which either aspires to inclusion or assimilation into the centre, or demands recognition of and respect for a separate but equal existence. This condition of marginality can be experienced in varying degrees by many kinds of people.

Often gender, sexual preference, age, ethnicity, geography and religion are factors which can influence perceptions of marginality. Those who perceive themselves, or who are perceived by others to be marginal are often female, dark-skinned, very young or elderly, poor, disabled, nonheterosexual, displaced, exiled, immigrant, rural, indigenous, 'foreign', outcast, persecuted, or otherwise 'different' from those who occupy positions of privilege in the centre, or the metropolis. Critics of the term 'marginality' believe it has become overused to the point of losing descriptive precision because, they argue, almost everyone has experienced some form of marginality. In philosophy, however, the phenomenon of feeling, or being, perceived as peripheral, or on the margin, has generated critical perspectives which have enlightened discourse on social integration and stratification; personal suffering and economic, political, and cultural inequality. In addition, analyses of marginality have called into question notions of the 'universal' and the 'objective' set forth by many Western philosophers.

AMY A. OLIVER

MARKET, ETHICS OF THE

Markets are systems of exchange in which people with money or commodities to sell voluntarily trade these for other items which they prefer to have. Most economic transactions in advanced societies are of this kind, and any attempt to replace markets

wholesale with a different form of economic coordination seems destined to fail. But questions about the ethics of markets are still of considerable practical concern, for two reasons at least. First, we need to make collective decisions about the proper scope of markets: are there goods and services which in principle should not be distributed and exchanged through market mechanisms – medical care, for instance? Second, markets work within a framework of property rights which sets the terms on which people can exchange with one another, and this too is subject to collective decision: for instance, should a person's labour be regarded as a commodity like any other, to be bought and sold on whatever terms the parties can agree, or does labour carry special rights that set limits to these terms? Are employees morally entitled to a share of the profits of the companies they work in, to take a concrete issue?

To guide such decisions, we need to apply general ethical principles to market transactions. First, are markets justified on grounds of efficiency, as is often claimed? What criterion of efficiency is being used when such claims are made? Second, can we regard the outcome of market exchanges as just, or, at the other extreme, should we see them as necessarily exploitative? Third, do market exchanges necessarily alienate people from one another and destroy their sense of community? These are very different questions, but an overall assessment of market ethics needs to address each of them, and perhaps others besides.

DAVID MILLER

MARX, KARL (1818–83)

Introduction

Karl Marx was the most important of all theorists of socialism. He was not a professional philosopher, although he completed a doctorate in philosophy. His life was devoted to radical political activity, journalism and theoretical studies in history and political economy.

Marx was drawn towards politics by Romantic literature, and his earliest writings embody a conception of reality as subject to turbulent change and of human beings as realizing themselves in the struggle for freedom. His identification with these elements in Hegel's thought (and his contempt for what he regarded as Hegel's apologetic attitude towards the Prussian state) brought Marx to associate himself with the Young Hegelians.

The Young Hegelians had come to believe that the implicit message of Hegel's philosophy was a radical one: that Reason could and should exist within the world, in contrast to Hegel's explicit claim that embodied Reason already did exist. Moreover, they also rejected Hegel's idea that religion and philosophy go hand in hand: that religion represents the truths of philosophy in immediate form. On the contrary, the Young Hegelians saw the central task of philosophy as the critique of religion – the struggle (as Marx himself was to put it in his doctoral dissertation) 'against the gods of heaven and of earth who do not recognize man's self-consciousness as the highest divinity'.

Marx came to be dissatisfied with the assumption that the critique of religion alone would be sufficient to produce human emancipation. He worked out the consequences of this change of view in the years 1843 to 1845, the most intellectually fertile period of his entire career. Hegel's philosophy, Marx now argued, embodied two main kinds of mistake. It incorporated, first, the illusion that reality as a whole is an expression of the Idea, the absolute rational order governing reality. Against this, Marx's position (and on this point he still agreed with the Young Hegelians) was that it is Man, not the Idea, who is the true subject. Second, he charged, Hegel believed that the political state – the organs of law and government – had priority in determining the character of a society as a whole. In fact, according to Marx, this is the reverse of the truth: political life and the ideas associated with it are themselves determined by the character of economic life.

Marx claimed that the 'species-being' of Man consists in labour, and that Man is 'alienated' to the extent that labour is performed according to a division of labour that is dictated by the market. It is only when labour recovers its collective character that men will recognize themselves as what they are – the true creators of history. At this point, the need to represent the essence of human beings in terms of their relation to an alien being – be it the Christian God or Hegelian *Geist* – will no longer exist.

In the mature writings that followed his break with the Young Hegelians, Marx presented a would-be scientific theory of history as a progress through stages. At each stage, the form taken by a society is conditioned by the society's attained level of productivity and the requirements for its increase. In pre-socialist societies this entails the division of society into antagonistic classes. Classes are differentiated by what makes them able (or unable) to appropriate for themselves the surplus produced by social labour. In general, to the extent that a class can appropriate surplus without paying for it, it is said to be an 'exploiting' class; conversely, a class that produces more than it receives is said to be 'exploited'.

Although the exploiting classes have special access to the means of violence, exploitation is not

generally a matter of the use of force. In capitalism, for example, exploitation flows from the way in which the means of production are owned privately and labour is bought and sold just like any other commodity. That such arrangements are accepted without the need for coercion reflects the fact that the ruling class exercises a special influence over ideas in society. It controls the *ideology* accepted by the members of society in general.

In *Das Kapital* (Capital), the work to which he devoted the latter part of his life, Marx set out to identify the 'laws of motion' of capitalism. The capitalist system is presented there as a self-reproducing whole, governed by an underlying law, the 'law of value'. But this law and its consequences are not only not immediately apparent to the agents who participate in capitalism, indeed they are actually concealed from them. Thus capitalism is a 'deceptive object', one in which there is a discrepancy between its 'essence' and its 'appearance'.

In Marx's view, it is inevitable that capitalism should give way to socialism. As capitalism develops, he believed, the increasingly 'socialized' character of the productive process will conflict more and more with the private ownership of the means of production. Thus the transition to collective ownership will be natural and inevitable. But Marx nowhere explained how this collective ownership and social control was to be exercised. Indeed, he had remarkably little to say about the nature of this society to the struggle to which he devoted his life.

The Critique of the Gotha Programme envisaged two phases of communist society. In the first, production will be carried out on a non-exploitative basis: all who contribute to production will receive back the value of what they have contributed. But this, Marx recognized, is a form of 'equal right' that leaves the natural inequalities of human beings unchecked. It is a transitional phase, although inevitable. Beyond it there lies a society in which individuals are no longer 'slaves' to the division of labour, one in which labour has become 'not only a means of life but life's prime want'. Only then, Marx thought, 'can the narrow horizon of bourgeois right be crossed in its entirety and society inscribe on its banners: from each according to his ability, to each according to his needs!' This is the final vision of communism.

1 Life and works

Marx was born on 5 May 1818, in Trier, a small, originally Roman city on the river Moselle. Many of Marx's ancestors were rabbis, but his father, Heinrich, a lawyer of liberal political views, converted from Judaism to Christianity and Marx was baptized with the rest of his family in 1824. At school, the young Marx excelled in literary subjects (a prescient schoolteacher comments, however, that his essays were 'marred by an exaggerated striving after unusual, picturesque expression'). In 1835, he entered the University of Bonn to study law. At the end of 1836, he transferred to Berlin and became a member of the Young Hegelian *Doktorklub*, a bohemian group whose leading figure was the theologian, Bruno Bauer. The views of the *Doktorklub* became increasingly radical (to some extent, it would seem, under Marx's influence) in the late 1830s.

Marx's father died in 1838 and in the next year – perhaps not coincidentally – Marx abandoned the law in favour of a doctorate in philosophy. His thesis, *Differenz der demokritischen und epikureischen Naturphilosophie* (Difference between the Democritean and Epicurean Philosophy of Nature) was accepted by the University of Jena in 1841. Marx had hoped to use it to gain an academic position, but, after Bruno Bauer's suspension from his post at the University of Bonn, it became apparent that such hopes would have to be abandoned in the current political climate.

Marx turned instead to journalism, involving himself with the newly-founded *Rheinische Zeitung* and taking over the editorship in October 1842. However, the paper came increasingly into conflict with the Prussian government and was banned in March 1843. At this point, Marx decided to move abroad. In the summer he married Jenny von Westphalen (after an engagement of six years) and during a long honeymoon in Kreuznach worked on *Zur Kritik der Hegelschen Rechtsphilosophie* (Critique of Hegel's Philosophy of Right) and the essay 'Zur Judenfrage' ('On the Jewish Question') in which he started to formulate his disagreements with his fellow Young Hegelians. He and Jenny moved to Paris in October of that year. It was in 1844 that Marx met up again with Friedrich ENGELS (whom he had known slightly in Berlin) and the alliance

was formed that was to last for the rest of Marx's life. Together Marx and Engels wrote *Die Heilige Familie* (The Holy Family) (1845), a polemic against Bruno Bauer. More important, however, was the body of writing on economics and philosophy that Marx produced at this time, generally known as the *Paris Manuscripts* (1844).

Marx was expelled from France in 1845 and moved to Brussels. In the spring of 1845, he wrote for his own clarification a series of essays on Feuerbach. These 'Theses on Feuerbach' are one of the few mature statements we have of his views on questions of epistemology and ontology. In 1845–6 Marx and Engels wrote *Die deutsche Ideologie* (The German Ideology) which, although it too remained unpublished, contains an authoritative account of their theory of history and in particular of the place of ideas in society. Marx's developing economic views were given expression in a polemic against Proudhon, *La Misère de la Philosophie* (The Poverty of Philosophy), published in 1847.

Das Kommunistische Manifest (The Communist Manifesto), written by Marx and Engels as the manifesto of the Communist League in early 1848, is the classic presentation of the revolutionary implications of Marx's views on history, politics and economics. During the revolutionary upsurge of 1848 Marx returned to Germany, but with the defeat of the revolutionary movement he was forced to leave, first for Paris, and then, in August 1849, for London, where he would live in exile for the rest of his life.

The years of exile in Britain were difficult ones for Marx (and even more so for his loyal and devoted family). He was in constant financial difficulty and had to rely heavily on Engels and other friends and relations for support. His theoretical activities were chiefly directed to the study of political economy and the analysis of the capitalist system in particular. They culminated in the publication of the first volume of *Das Kapital* (Capital) in 1867. However, *Das Kapital* is the tip of a substantial iceberg of less important publications and unpublished writings. Among the former, the Preface to *Zur Kritik der politischen Ökonomie* (A Contribution to the Critique of Political Economy) published in 1859, contains the classic statement of Marx's materialist theory of history. The second and third volumes of *Das Kapital*, left unfinished at Marx's death, were edited and published posthumously by Engels. In addition, three volumes of *Theorien über den Mehrwert* (Theories of Surplus-Value), a series of critical discussions of other political economists, written in 1862–3, were published in the early twentieth century. An extensive and more or less complete work, the *Grundrisse der Kritik der politischen Ökonomie* (known both in English and in German as the *Grundrisse*) was written in 1857–8 but only published in 1939. The Introduction to the *Grundrisse* is the mature Marx's most extended discussion of the method of political economy. In addition, there exist numerous notebooks and preliminary drafts, many (if not, at the time of writing, all) of which have been published.

Political economy apart, Marx wrote three works on political events in France: *Die Klassenkämpfe in Frankreich* (Class Struggles in France) (1850), *Das achtzehnte Brumaire des Louis Bonaparte* (The Eighteenth Brumaire of Louis Bonaparte) (1852) and *The Civil War in France* (1871). Among his many polemical writings, the *Kritik des Gothaer Programms* (Critique of the Gotha Programme) (1875) is particularly important for the light it throws on Marx's conception of socialism and its relation to ideas of justice.

Marx was in very poor health for the last ten years of his life, which seems to have sapped his energies for large-scale theoretical work. However, his engagement with the practical details of revolutionary politics was unceasing. He died on 14 March 1883 and is buried in Highgate Cemetery, London.

2 Marx as a Young Hegelian

Marx is relevant to philosophy in three ways: (1) as a philosopher himself, (2) as a critic of philosophy, of its aspirations and self-understanding, and (3) by the philosophical implications of work that is, in Marx's own understanding of it, not philosophical at all. Broadly speaking, these three aspects correspond to the stages of Marx's own intellectual development. This and the following section are concerned with the first stage.

The Young Hegelians, with whom Marx was associated at the beginning of his career, did not set out to be critics of Hegel. That they rapidly became so has to do with the consequences they drew from certain tensions within Hegel's thought. Hegel's central claim is that both nature and society embody the rational order of *Geist* (Spirit). Nevertheless, the Young Hegelians believed, it did not follow that all societies express rationality to the fullest degree possible. This was the case in contemporary Germany. There was, in their view, a conflict between the essential rationality of *Geist* and the empirical institutions within which *Geist* had realized itself: Germany was 'behind the times' (see Hegel, G.W.F. §§5–8; Hegelianism).

A second source of tension lay in Hegel's attitude towards religion. Hegel had been prepared to concede a role to religion as the expression of the content of philosophy in immediate form. The

Young Hegelians, however, argued that the relationship between the truths of philosophy and religious 'representation' was, in fact, antagonistic. In presenting reality not as the embodiment of reason but as the expression of the will of a personal god the Christian religion establishes a metaphysical dualism that is quite contrary to the secular 'this-worldliness' which (although Hegel himself might have been too cautious to spell it out fully) is the true significance of Hegel's philosophy.

This was the position endorsed by Marx at the time of his doctoral dissertation on Epicurus and Democritus. Its subject was taken from a period of Greek thought that displayed parallels with the Germany of Marx's own time. Just as the Young Hegelians faced the problem of how to continue philosophy after Hegel, so Epicurus wrote in the shadow of another great system, that of Aristotle. Epicurus is more successful than Democritus, Marx believes, in combining materialism with an account of human agency. Furthermore, Marx admires Epicurus for his explicit critique of religion, the chief task of philosophy, he asserts, in all ages.

In its destruction of the illusions of religion, the Young Hegelians believed that philosophy would provide both the necessary and the sufficient conditions for human emancipation and the achievement of a rational state. In the works that he wrote in Kreuznach in 1843 (the unpublished draft of the *Critique of Hegel's Philosophy of Right* and the essay 'On the Jewish Question') and shortly thereafter (the '*Critique of Hegel's Philosophy of Right*: Introduction') Marx called this position into question.

In the *Critique of Hegel's Philosophy of Right* Marx makes two main criticisms of Hegel. The first is that Hegel's real concern is to retrace in the political realm the outlines of his own metaphysics, rather than to develop an analysis of political institutions and structures in their own right. This gives his political philosophy an apologetic function, for it leads him to present the contradictions that he finds in reality as essentially reconciled in the supposedly higher unity of the 'Idea'. But they are not, says Marx. On the contrary, they are 'essential contradictions'.

Chief among such contradictions is that existing between the 'system of particular interest' (the family and civil society – that is, economic life) and the 'system of general interest', namely, the state. And this leads to Marx's second criticism. Hegel, Marx alleges, assumes that the state, because it is 'higher' from the point of view of Hegelian logic, can effectively reconcile the contradictions of economic life. In fact, in Marx's view, it is civil society that exists prior to the state. The state arises from the condition of civil society and is always subordinate to the form of the latter.

3 Philosophy and the critique of religion

Marx presents the implications of these criticisms for the critique of religion in the *Critique of Hegel's Philosophy of Right*: 'Introduction'. This short essay is a compressed masterpiece of vehement rhetoric, seething with antithesis and chiasmus. In Germany, Marx writes, 'the critique of religion is essentially completed'. Thus the problem is how to go beyond it. Marx's first step is to explain the significance of that critique, as he understands it.

The world of religion is a reflection of a particular form of society: 'This state, this society, produce religion, which is an inverted world-consciousness, because they are an inverted world'. That is to say, only an inverted, secular world would produce religion as its offshoot. In religious belief, Man finds himself reflected in the 'fantastic reality of heaven', whilst he can find only 'the semblance of himself, only a nonhuman being' in this world. Religion thus provides a realm in which individuals can realize themselves, at least partially, given that full and adequate self-realization is not possible in the profane world. In this way, religion preserves the social order of which it is a by-product, both by deflecting attention from its defects and by providing a partial escape from it. In Marx's famous words, 'Religion is the sigh of the oppressed creature, the heart of a heartless world and the soul of soulless conditions. It is the opium of the people'.

Thus religion and the form of life associated with it are open to criticism at three points. (1) There is, first, the impoverished and distorted world of which religion is a by-product. (2) There is the way in which the image of reality produced by religion is falsely transfigured. (3) Finally, there is the failure by human beings to recognize the fact that religion has its origins in mundane reality.

It is this last element towards which the critique of religion is directed. Critique of religion connects religion back to its unacknowledged origins in social existence. Yet this is not enough. The critique of religion, inasmuch as it is a call to people to abandon their illusions, is also, according to Marx, 'the call to abandon a condition that requires illusions'. By itself the critique of religion cannot remove the distortion and impoverishment of the world from which religion arises. This is of course Marx's real project, for which the criticism of religion has merely prepared the ground.

Once the criticism of religion has done its work, philosophy must move on 'to unmask human self-alienation in its secular forms'. The critique of religion ends, Marx says, 'in the doctrine that man is the supreme being for man; thus it ends with the categorical imperative to overthrow all conditions in

which man is a debased, enslaved, neglected, contemptible being' (*Zur Kritik der Hegeleschen Rechtsphilosophie* 1843).

Much of this analysis represents common ground between Marx and his Young Hegelian former associates. Marx concedes that philosophy has both a critical role to play in exposing the illusions of religion and an affirmative one in establishing an ideal of human fulfilment. Nevertheless, Marx takes the Young Hegelians to task for thinking that philosophy alone provides a sufficient condition for human emancipation. Philosophy, he maintains, must move beyond itself: 'criticism of the speculative philosophy of right does not remain within itself, but proceeds on to tasks for whose solution there is only one means – praxis'. For this, a material force – a 'class with radical chains' – is required, namely, the proletariat.

At this stage, then, Marx is critical not so much of the content of philosophy, but of what we might call the metaphilosophical belief associated with it: that it is possible (as he puts it in relation to the Young Hegelians) 'to realize philosophy without transcending it'. A truly successful critique of religion would require the transformation of the social conditions within which religion is generated and sustained.

4 Alienated labour

In Paris, Marx threw himself into the study of political economy. His objective was to amplify his critique of Hegel and the Young Hegelians with a more far-reaching account of the nature of 'civil society'. The *Paris Manuscripts* thus provide a unique link between Marx's economic theory and his philosophical view of human nature. The concept which brings the two together is that of alienation (*Entfremdung*) (see ALIENATION). Although Marx had made little use of this term in his earlier writings, the structure of the concept is clearly anticipated in his critique of religion. The fundamental idea is that an entity or agent gives rise to a product or expression that is distinct from but at the same time essential to itself. This secondary product comes to be cut off from its origin. In consequence, the agent suffers a loss of identity in some sense. Thus, for the agent to realize itself fully, it must remove the separation that has come between itself and its own product.

In the central discussion of the *Paris Manuscripts*, Marx sets out to apply the concept of alienation to the labour process. Alienation, Marx argues, is characteristic of a situation in which (1) labour is directed towards the production of commodities (that is, goods exchangeable in the market) and (2) labour itself is such a commodity. Marx divides the alienation involved in labour into three main forms.

(1) There is, first, the separation of the worker from the product of labour. It is in the nature of the labour process that it involves 'appropriating' the external world. But when labour is alienated, the sensible, external world becomes an object to which the worker is bound, something that is hostile to them, instead of being the means to their self-realization.

(2) At the same time, the labour process itself becomes alien to the worker. Because the imperatives according to which labour takes place come to the worker 'from outside' (that is, from the market, either directly or indirectly) labour is no longer an act of self-realization. It becomes, from the worker's point of view, 'an activity directed against himself, which is independent of him and does not belong to him'.

(3) Finally, Marx says, the consequence of these two forms of alienation is to alienate man from what he calls his 'species-being' (*Gattungswesen*). The latter concept (of which Marx made frequent use in 1843–4) is adapted from Ludwig Feuerbach. Man, says Marx, is a species-being 'because he looks upon himself as the present, living species, because he looks upon himself as a *universal* and therefore free being'.

An analogy that may help to clarify this apparently circular definition can be made with the family. In a limited sense, people can be part of a family without consciously behaving accordingly (at the limit, we can think of members of a family who do not even know that they are related). But in order to be a family in a fuller sense, people must relate to one another *as* a family, and at least a part of this is that they should be aware that they *are* a family. So it is with human species-being. While the fundamental phenomenon on which the family is based is a biological relation, in human species-being it is labour. Thus, as labour is alienated in other respects, so people become alienated from their species-being. The consequence is the alienation of members of the species from one another.

Each of these three points is, one might think, somewhat questionable. Surely, in any situation in which individuals do not produce entirely for themselves, it will be inevitable that the products of labour are 'separated' from the original producer. Likewise, the labour process cannot be something that is freely chosen by individuals as long as they are objectively constrained by the nature of the material world and the resources available to them in finding efficient means to given ends. Finally, it is not at all clear what is involved in human beings 're-appropriating' their 'species-being'.

One way of making the concept of alienated labour more precise is to ask what it might be for

labour to be non-alienated. Marx addresses the issue at the end of a discussion of James Mill's *Elements of Political Economy.* 'Let us suppose', Marx begins, 'that we had produced as human beings'. In that case, he claims, each of us would have 'affirmed' both ourselves and our fellows in the process of production. In the first place, I, the producer, would have affirmed myself in my production. At the same time, I would be gratifying a human need – that of my neighbour, for whom I am in this case producing. Thus, in meeting your need, I would have mediated between you and the species: 'I would be acknowledged by you as the complement of your own being, as an essential part of yourself'. In this way, production and the meeting of needs involves a mutuality of self-realization and reciprocal recognition:

> In the individual expression of my own life I would have brought about the expression of your life, and so in my individual activity I would have directly *confirmed* and *realized* my authentic nature, my *human*, *communal* nature.
> (*Paris Manuscripts*)

These ideas help to explain Marx's antagonism towards what he would call 'bourgeois' political theory. In so far as traditional political philosophy takes as its fundamental question how to reconcile competing interests, its starting point is, from Marx's point of view, unacceptably individualistic. For what entitles us to assume that the interests of individuals are bound to be antagonistic? Rather than asking how to allocate rights and duties fairly when interests conflict, the task, Marx believes, is to move humanity towards a form of life in which conflicts of interest are no longer endemic.

5 The critique of philosophy

Although the *Paris Manuscripts* show Marx's increasing engagement with political economy, they do not represent an abandonment of his concern with philosophy. The attitude that Marx takes towards philosophy, however, now becomes more critical than it had been in his earlier, Young Hegelian period. In part, this can be traced to Ludwig Feuerbach, whom Marx quotes approvingly at several points (see FEUERBACH, L.). It was Feuerbach's great achievement, Marx writes, 'to have shown that philosophy is nothing more than religion brought into thought and developed in thought, and that it is equally to be condemned as another form and mode of existence of the alienation of human nature'. Thus Marx now regards philosophy as essentially continuous with religion, not a force directed against religion, as he had represented it at the time of his doctoral dissertation.

Marx makes a number of negative remarks regarding philosophy in general, but his more specific critical comments are directed towards Hegel. Like Feuerbach, he takes the view that Hegel has brought philosophy to a point of completion. The dynamic principle at the heart of Hegel's philosophy, according to Marx, is that of 'abstract mental labour'. Nevertheless, despite the genuinely critical elements contained within it, Hegel's philosophy is vitiated by its idealist assumptions. In the end, for Hegel, alienation is merely a matter of the separation of the products of thought from thought itself, something to be overcome by a philosophical reorientation of consciousness. To go beyond Hegel, it would be necessary to make the concept of real, concrete labour fundamental. But this, Marx suggests, leads beyond philosophy itself.

Marx pursues these ideas in the 'Theses on Feuerbach', written in the spring of 1845. Here he makes it explicit that his disagreement is not only with idealistic philosophies, such as Hegel's, but also with would-be materialist ones, Feuerbach's included. In incorporating within itself an idea of 'activity', idealism has important advantages over materialism. It is, Marx writes,

> the chief defect of all hitherto existing materialism (that of Feuerbach included) . . . that the thing, reality, sensuousness, is conceived only in the form of the object or of contemplation, but not as sensuous human activity, praxis, not subjectively. Hence, in contradistinction to materialism, the *active* side was developed abstractly by idealism – which, of course, does not know real sensuous activity as such.
> ('Theses on Feuerbach')

It should be noted that this passage is ambiguous. Is Marx envisaging a new kind of materialism (one that would not have the defects of 'hitherto existing materialism') or is it a call to leave philosophy – both materialism and idealism – behind altogether? Interpreters of Marx who take the former view have ascribed an implicit philosophical position to him (often called 'dialectical materialism'). Nevertheless, the fact remains that Marx himself never developed such a position explicitly, and the conclusion of the 'Theses on Feuerbach' appears to lead away from philosophy entirely: 'The philosophers have only *interpreted* the world in various ways; the point is to *change*it.'

The German Ideology, which Marx and Engels wrote from September 1845 to the summer of 1846, continues this line of argument. As in so

many of Marx's writings, the rhetorical trope from which the criticism starts is that of an inversion of an inversion. The Young Hegelians, Marx alleges, think of themselves as engaged in a struggle with the illusions that hold the Germans in their grip. But in fact they are in the grip of an illusion themselves: the illusion that ideas are an independent, determining force in political life. Feuerbach is not excepted from this criticism. Although he purports to demystify the realm of pure ideas, he still remains, according to Marx and Engels, 'in the realm of theory'. Feuerbach, they claim, 'never arrives at really existing, active men, but stops at the abstraction "man"'.

The alternative that Marx and Engels propose is, of course, also a theory, but it is a theory, they claim, of a quite different kind. 'In direct contrast to German philosophy, which descends from heaven to earth', their purpose is to present an account which will 'ascend from earth to heaven'. Instead of translating general ideas back into equally general anthropological categories, the aim is to give a specific account of their historical origins. In so doing, it undermines the presuppositions on which the philosophical enterprise rests and philosophy, as an independent branch of knowledge, loses its medium of existence:

> The philosophers would only have to dissolve their language into the ordinary language, from which it is abstracted, to recognize it as the distorted language of the actual world, and realize that neither thoughts nor language in themselves form a realm of their own, that they are only *manifestations* of actual life.
>
> (*The German Ideology*)

6 The theory of ideology: (1) The reflection model

The German Ideology is filled with polemical assertions of the priority of material life over the world of religion, thought and speculation. But it sets out to do more than sloganize. Its aim is to develop the framework for a scientific explanation of how the material life conditions and determines thought and culture. By the time *The German Ideology* came to be written, the term 'ideology' had established itself in German as referring to systems of ideas detached from and out of proportion to empirical reality (Heinrich Heine, with whom Marx was on intimate terms in Paris, used it in that sense). In *The German Ideology* this is certainly part of the meaning of the term. But the concept also has a wider explanatory function (see IDEOLOGY).

Since the ancient world, political thinkers had been concerned with the role that 'false' or irrational forms of consciousness play in political life. To this extent, the Young Hegelian critique of religion represented the latest manifestation of a very long tradition. However, the originality of Marx's concept of ideology lies in the way that it brings the idea of false consciousness together with a distinctively modern conception of society.

At the end of the eighteenth and the beginning of the nineteenth century, a conception of society came to the fore in Germany and France according to which societies, like organisms, have the power of maintaining and reproducing themselves through time. Marx was very much taken with this view, which he endorsed in the *Critique of Hegel's Philosophy of Right*. Chief among the conditions for a society to reproduce itself, according to Marx, are the ideas held by its members. Thus false consciousness, rather than being simply an accidental feature of human nature (albeit one with enormous political consequences) should be regarded as a phenomenon to be explained by the particular character of the society in which it is to be found.

If societies do not rest solely on coercion, then this is because those who are oppressed or exploited for some reason accept this. As Marx puts it bluntly: 'the ideas of the ruling class are in every epoch the ruling ideas'. But how does this come about? What sort of connection holds between the economic structures of a society and the ideas of its members? *The German Ideology* contains two analogies that might serve as mechanisms for the explanation of the connection between material life and ideas. The first is embodied in the following famous passage:

> If in all ideology men and their circumstances appear upside-down as in a camera obscura, this phenomenon arises just as much from their historical life-process as the inversion of objects on the retina does from their physical life-process . . . . We set out from real, active men, and on the basis of their real life-process we demonstrate the development of the ideological reflexes and echoes of this life-process. The phantoms formed in the human brain are also, necessarily, sublimates of their material life-process, which is empirically verifiable and bound to material premises.
>
> (*The German Ideology*)

Let us call this the 'reflection model' of ideology. The idea is that ideology relates to material life as images do to reality in a camera obscura or on the retina of the human eye: items in reality are reproduced accurately, but in reverse.

Yet brief consideration of the analogy shows that, as it stands, it is completely inadequate. It is indeed true that the images on the human retina are

'upside-down'. But does this mean that human beings do not perceive the world about them accurately? Of course not. The fact is that, as far as human perception is concerned, 'upside-down' is the right way up for images to be on our retinas. And this points the way towards the problem with Marx's analogy. By describing *all* consciousness as reversed or inverted the contrast between 'true' and 'false' loses its sense.

A further objection arises later in the quoted passage in which Marx continues the reflection analogy when he speaks of the ideological 'reflexes and echoes' of real life-processes. Ideological ideas are, he goes on to say, 'phantoms' and 'sublimates'. These metaphors carry with them an important implication: ideological thought is the effect of real processes, but it is itself insubstantial, without material reality or causal power. If this is Marx's considered view, then it is clearly disastrous for the theory of ideology. For the point of the theory of ideology was to explain how it was that certain forms of thought served to sustain particular societies. Thus these forms of thought are, by assumption, not ineffective, but have very important causal effects: helping to maintain a particular social and economic order.

Finally, it is not obvious that ideology relates to material life as mind relates to matter. Is the implication that ideology is immaterial and material life non-intellectual? This plainly contradicts Marx's basic position. Not only would it be odd for an avowed materialist to suggest that ideas are something basically insubstantial, but, even more importantly, it conflicts with the idea that economic life, so far from being unconscious or unreflective, is the central part of man's cognitive engagement with external reality.

7 The theory of ideology: (2) The interests model

There is, however, another model at work in *The German Ideology*. While the reflection model draws on the parallel between the ideological process and a traditional, realist account of perception (the immaterial mind passively mirrors a mind-independent reality) what we may call the 'interests model' develops from a more instrumentalist approach to epistemology. That Marx was (at this time, at least) attracted to such views is apparent from the 'Theses on Feuerbach'. In the second thesis he writes, 'The dispute over the reality or non-reality of thinking that is isolated from practice is a purely *scholastic* question'. From this point of view, the most significant aspect of ideas is not their relationship to a mind-independent reality, but that they are the products of practical activity, and that this practical activity is itself guided by interests. The materialistic view of history that this leads to, Marx and Engels say, 'does not explain practice from the Idea, but explains the formation of ideas from material practice'.

The problem with the interests model does not lie in the view that ideas are the product of interests itself, which is, of course, very plausible (although it is more difficult to determine just what proportion of our ideas are products of interests in this way – surely not all of them – and to explain just how it is that interests should assert themselves in the process by which ideas are formed). The problem is that ideological ideas are not simply ideas formed in the pursuit of interests. They are, in fact, supposed to be ideas that go *against* the interests of a large number of those who hold them (and in this way further the interests of others). How do ideas of this kind come to be accepted?

Marx and Engels' answer starts from the following claim:

> The class which has the means of material production at its disposal, has control at the same time over the means of mental production, so that thereby, generally speaking, the ideas of those who lack the means of mental production are subject to it.
>
> (*The German Ideology*)

But this is not a satisfactory solution. Marx and Engels seem to view those who live under the domination of the ruling class as passive victims, taking their ideas like obedient chicks from those who control the 'means of mental production', with no critical reflection as to whether the ideas are either true or in their own rational interests. Yet why should one suppose that the ruling class is capable of promoting its interests effectively and forms its ideas in response to those interests, while the dominated classes simply accept whatever is served up to them?

Marx and Engels do, however, attempt to make their claim more plausible in their discussion of the nature of mental production. It is, they write, the most significant development in the division of labour that mental and manual labour become separated:

> Division of labour only becomes truly such from the moment when a division of material and manual labour appears.... From this moment onwards consciousness *can* really flatter itself that it is something other than consciousness of existing practice, that it *really* represents something without representing something real; from now on consciousness is in a position to emancipate itself from the

> world and to proceed to the formation of 'pure' theory, theology, philosophy, ethics, etc.
> (*The German Ideology*)

The separation between mental and manual labour, Marx and Engels maintain, does not really lead to the formation of autonomous ideas; the ideologists who produce ideas are still part of the ruling class whose interests their ideas represent. Nevertheless, it offers an explanation as to why such ideas should be accepted by those, the dominated classes, whose interests they oppose: they are accepted because they are apparently disinterested. The ideologist, on this view, is like a bribed referee: able to influence the outcome of a game all the more effectively for the fact that he is falsely believed to be impartial.

Are ideologists, then, engaged in deception? Do they know the partiality of their ideas but present them none the less as if they were neutral and disinterested? On the contrary. According to Marx and Engels, ideologists are sincere – and, because they sincerely believe in the independence and objective validity of their own ideas, they are able to persuade others to accept them as such all the more effectively. Herein, however, lies the problem. How are we to suppose it to be true that the ideologists should both be constrained so that they produce ideas in the interests of the ruling class of which they are, appearances to the contrary, a part, and that they (and those who accept the ideas from them) remain sincerely unaware of the nature of this connection? Why do they *think* that they are independent when in fact they are not? And, if they are not independent, how do the class interests they share with the rest of the ruling class assert themselves?

In any case, it is clear why Marx should now become so hostile to philosophy: like any supposedly 'pure' theory, philosophy represents a deceptive abstraction from the particular circumstances and material interests that it serves. This move to detach ideas that are the products of material interests from the interests that they represent is epitomized, for Marx and Engels, in Kant (the 'whitewashing spokesman' of the German bourgeoisie, as they call him). Kant, they write:

> made the materially motivated determinations of the will of the French bourgeois into *pure* self-determinations of 'free will', of the will in and for itself, of the human will, and so converted it into purely ideological determinations and moral postulates.
> (*The German Ideology*)

For Marx and Engels, at this stage at least, 'moral postulates' are, by their very nature, ideological.

8 Historical materialism

'Where speculation ends – in real life – there real, positive science begins', according to Marx and Engels in *The German Ideology.* The science to which they are referring is the materialist theory of history, whose classic statement is given in the Preface to *Zur Kritik der politischen Ökonomie* (A Contribution to the Critique of Political Economy) (1859).

Taken most generally, the materialist theory of history asserts that the manner in which human beings produce the necessities of life determines the form of the societies in which they live. Every society other than the most primitive produces a 'surplus' beyond what it immediately consumes. The manner in which this surplus is 'appropriated' – taken from the direct producers and redistributed – determines the class structure of the society in question. If society is divided between direct producers and those who benefit from the former's 'unpaid surplus labour' (something that is true of all societies where a surplus exists, prior to the advent of socialism) the relationship between classes is antagonistic.

At any stage, the size of the surplus is an expression of the level of development of the 'productive forces' – the resources, physical and intellectual, upon which material production draws. Every society contains both an economic 'base', composed of 'relations of production' (the relations producers have to the means of production and to one another) and a legal and political 'superstructure', corresponding to the base. The relations of production favour the development of the productive forces up to a point. Beyond this they become, Marx says, 'fetters' upon the forces of production, and a conflict arises which leads eventually to the replacement of the existing relations of production with new and superior ones.

Presented in these terms, it is clear that the materialist theory of history is intended as an exercise in social science rather than philosophy. Thus it may seem surprising that it should have attracted such enduring attention on the part of philosophers. However, scientific theories may be of concern to philosophers if their assumptions are novel, obscure or questionable, even if the intentions behind them are in no way philosophical (examples are Darwin, Freud and Newton). In the case of Marx's theory of history, it is not just the meaning of and evidence for the particular claims to be found in the theory that have been controversial. The more general issues of the form of explanation that Marx employs and the kind of entities such an explanation presupposes have been continuing matters of dispute.

Interpreters of Marx divide broadly into three groups on these questions. In the first are those for

whom Marx's theory of history is intended to be scientific in the way that any other scientific theory is. With some qualifications, the majority of the earliest Marxists (for example, Engels himself, Kautsky and Plekhanov) fall into this group. On the other hand, those who believe that there is a contrast between Marx's conception of science and the natural sciences may be divided into those who see Marx's theory as a transformation of Hegel's theory of history and those for whom it is fundamentally anti-Hegelian. The most influential presentation of the former interpretation is to be found in Georg Lukács' *History and Class Consciousness* (1921), while the latter is particularly associated with the French philosopher, Louis Althusser (see ALTHUSSER, L.P.; LUKÁCS, G.; PLEKHANOV, G.V.).

In the late 1970s the first approach was revived in the English-speaking world by G.A. Cohen's seminal *Karl Marx's Theory of History: A Defence* (1978). According to Cohen, historical materialism can be presented in a way that contains nothing that should be unacceptable to anyone who accepts the legitimacy of Darwinian biology (see DARWIN, C.R.).

The two theories are, in Cohen's view, importantly parallel to one another, for both employ 'functional explanation' (see FUNCTIONAL EXPLANATION). When Marx says that the relations of production *correspond* to the forces of production, what he means, according to Cohen, is first that the relations are in some sense 'good for' the (development of the) forces and second that they obtain *because* they are good for the forces. (The same analysis, suitably adapted, applies to the correspondence between superstructure and base.) What is distinctive about Darwinian biology, however, is not just that it employs functional explanation, but that it provides a convincing account (what Cohen calls an 'elaborating explanation') of why its functional explanations are true: the process of natural selection. Does Marxism have an equivalent elaborating explanation?

All the indications are that it does not. In response to this, there have been two main lines of argument. One is that the theory should have (but lacks) such an explanation and that it is the task of a sympathetic reconstruction of Marx to provide one. On the other hand, it is also possible to argue that the search for what Jon Elster has called 'micro-foundations' is misguided. Thus the functional explanations that Marx invokes in the theory of history rest on the fact that there really are collective agents (classes, for example). On this 'collectivist' reading it is sufficient simply to appreciate the nature of collective agency to see why collective agents should feature in functional explanations: they have the power to act purposively to bring about their ends. No reductive 'elaborating explanation' is necessary.

To take this view is to align oneself with the second and third groups of Marx's interpreters and to affirm the fundamental gap between Marx's theory of history and the explanations of the natural sciences (where functional explanations are not simply left unelaborated). If so, the Marxist theory of history cannot draw on the general prestige of science for its justification.

9 Political economy

In contrast to his relatively brief and schematic statements concerning general history, Marx wrote very extensively about the economic system under which he himself lived. *Das Kapital*, which presents Marx's definitive analysis of capitalism, is a work of exceptional methodological complexity, as is already suggested by its sub-title, 'Critique of Political Economy'. The phrase is ambiguous. Is Marx's objective to criticize the bourgeois economy or bourgeois economics? In fact, Marx rejects this as a false antithesis: the subject matter of the book is both. Ten years before its publication, Marx described the work that was to become *Das Kapital* in a letter: 'The . . . work in question is a *critique of the economic categories*, or, if you like, the system of bourgeois economy critically presented. It is a presentation [*Darstellung*] of the system and, simultaneously, a critique of it'.

The two aspects go together in Marx's view because economic categories are not simply the means employed by an observer to classify some inert mass of data. They are themselves a part of social reality, 'abstract forms' of the social relations of production.

Bourgeois economists, Marx alleges, characteristically fail to recognize that their categories are specific to capitalism, and so they treat the capitalist mode of production as one 'eternally fixed by nature for every state of society', Marx alleges. A 'critical presentation' of economics must counteract the false eternalization of the economy that bourgeois economics carries within itself.

As it stands, this is a criticism of the limitations in the self-understanding of bourgeois economics rather than a challenge to its empirical content. Yet empirical explanation is a central part of Marx's project. 'It is', he writes in the Preface to *Das Kapital*, 'the ultimate aim of this work to lay bare the economic law of motion of modern society.' Has bourgeois economics failed to discover this law or has it simply not put its categories in historical context? At its strongest, Marx's case is that both criticisms are true and that the former failing is a result of the latter. The 'law of value' that Marx claims to have discovered could not, he says, have been discovered by economic science 'so long as it is stuck in its bourgeois skin'.

The connection that Marx sees between the categories of economic life and the categories of economic analysis is made more complicated by the structure that he ascribes to capitalism. Marx believes that an indispensable ingredient for understanding capitalism is the contrast between its 'essence' – its underlying determinants – and its 'appearance' – the way that it immediately strikes those who live in it. Corresponding to this distinction are two kinds of bourgeois economic thought: what Marx calls 'classical economy', on the one hand, and 'vulgar economy' on the other. Classical economy (the tradition whose greatest representatives were Ricardo and Adam SMITH) aims towards the essence of capitalism: it 'nearly touches the true relation of things', although it is not able to formulate that relation explicitly. According to Marx, it is the mark of the 'vulgar economy' of his own time, by contrast, that it 'feels particularly at home in the alienated outward appearances of economic relations'. Yet this means that it is fundamentally unscientific, for 'all science would be superfluous if the outward appearance and the essence of things coincided'. A truly scientific political economy must go beyond the immediately received categories of economic life. This is what Marx believes that he himself has achieved (and he considers himself for this reason to be the heir of the tradition of classical political economy).

In a letter to Engels, written at the time of the publication of the first volume of *Das Kapital*, Marx singles out what he calls the 'twofold character of labour' as the most important point in his book. Labour, Marx claims, is both the source of value and, at the same time, under capitalism, a commodity itself. Yet this commodity (labour-power, as Marx calls it) is a commodity of a special kind. Its value is not the same as the value of the commodities produced by the labour that is exercised on behalf of its purchaser, the capitalist. This discrepancy, in Marx's view, explains the 'origin' of surplus-value – the fact that the capitalist appropriates the surplus-labour of the worker under the guise of a fair exchange. In discussing the manner in which, in capitalist society, labour is sold to capitalists as a commodity, in exchange for wages, Marx writes: 'Hence we may understand the decisive importance of the transformation of the value and price of labour-power into the form of wages, or into the value and price of labour itself. This phenomenal form, which makes the actual relation invisible, and, indeed, shows the direct opposite of that relation, forms the basis of all the juridical notions of both labourer and capitalist, of all the mystifications of the capitalist mode of production, of all its illusions as to liberty, of all the apologetic shifts of the vulgar economists'.

Thus we see Marx making three claims: (1) that we should see reality as layered, having a surface appearance governed by an underlying structure; (2) that to make such a distinction is characteristic of the scientific approach to reality in general; and (3) that the phenomenal form conceals the real relations (it 'makes the actual relation invisible and indeed shows the opposite of that relation').

However, claims (1) and (2) do not entail (3). According to claims (1) and (2) (in themselves extremely plausible) the way that we see the world is not, immediately, adequate for us to explain the way that the world is. But that does not make our immediate perception of the world false. It simply lacks a theory. Yet Marx's claim (3) is much stronger: reality presents itself in a way that deceives those who immediately perceive it. Marx's own statements to the contrary, it seems that this third claim is best understood not as a general consequence of the nature of scientific understanding but as a specific feature of capitalism. Capitalism mystifies those who live under it, Marx believes, because it is a 'deceptive object'. To penetrate its surface scientifically it is necessary to go beyond the limitations of bourgeois political economy.

10 The fetishism of commodities

The most detailed discussion that Marx provides of a case where the surface of capitalism presents itself as 'false' is to be found in 'The Fetishism of Commodities and the Secret Thereof', in *Das Kapital*. This discussion is a recognizable reworking of the central themes to be found in the treatment of alienated labour in the *Paris Manuscripts*.

In the eighteenth-century sense of the term, fetishists were those non-European peoples whose religion involved the worship of inanimate objects. Fetishism is a fallacy attributing to objects in the world some quality (power and personality) that they, in fact, lack. Marx's conception of commodity fetishism shares this structure, but differs in an important way. The fetishism of commodities is not a matter of subjective delusion or irrationality on the part of perceivers, but is somehow embedded in the reality that they face.

According to Marx, two separate facts or properties are distorted in the commodity-form. First, the 'social character' of human beings' labour appears (falsely) as 'objective characteristics of the products themselves', and second (in consequence of the first fact, as Marx asserts) the producers' own relationship to their 'collective labour' appears 'as a social relationship between objects, existing externally to the producers'.

The first issue concerns what the 'social character' that is apparently a property of the

products themselves amounts to. Is it the sheer fact that the commodity *is* a commodity? This suggestion must be rejected, for the belief that the product is a commodity is in no way a false or deceptive one. Likewise, it cannot be something concealed from the producers that commodities *do* as a matter of fact exchange for one another in certain proportions: it is hard to see how anyone could live their lives within a market society without having an adequate understanding of facts of this kind (enough, at least, to be able to buy something to eat). The best interpretation of Marx's argument is that it is not such first-order facts about commodities but a second-order one that is the source of deception: it is not *that* commodities can be exchanged with one another in certain ratios but *the reason why* they exchange in the ratios that they do that is their hidden secret.

Marx's account of the illusion regarding the social character of the products of labour is complemented by the account he gives of the second element in commodity fetishism. Because commodity production takes place as a process by which the producers' activities are coordinated solely through the imperatives of a system of market exchanges, it follows, Marx says, that 'the social relations between their private acts of labour manifest themselves as what they are – that is, not as the immediate social relationships of persons in their labour but as material relationships between persons and social relationships between things'.

Implicitly, the market commensurates the labour of each individual with the labour of every other producer – individual labour has its value in relation to the way in which others perform the same labour. The socially useful character of the labour of the individual producers thus appears to them, according to Marx, 'only under those forms which are impressed upon that labour in everyday practice, in the exchange of products'.

Here again, Marx is indicating an illusion of the second rather than the first order. The individual producers are aware of the role of the market in determining the way in which they labour. In this they are quite correct. But they also believe (falsely) that it is the market that makes their labour useful (rather than recognizing it as a contingent fact about capitalist production that their socially useful labour takes on a market-determined form). Society generates such false beliefs spontaneously, Marx claims. The world of commodities 'veils rather than reveals', he says, the social character of private labour and of the relations between the individual producers.

That the true source of the value of commodities lies in the labour expended in their production is, Marx maintains, a matter of simple scientific truth. So, too, is the fact that the social character of private labour consists in the equalization of that labour under the auspices of the market. Nevertheless, fetishism is a matter of 'objective illusion' and knowledge of these truths does not dispel such false appearance. The discovery of the law of value 'by no means dissipates the objective illusion through which the social character of labour appears to be an objective character of the products themselves' any more than 'the discovery by science of the component gases of air' altered the atmosphere that people breathed.

The analogy that Marx chooses here is not a happy one. Admittedly, it is absurd to think that a scientist's discovery about an object should change the object itself. But that is not the issue. It is not a question of whether the atmosphere itself changes after the discovery of its component gases, but whether the way in which we think about it changes. It is only if we suppose that capitalism, unlike the atmosphere, is an object of a particular kind – a deceptive object – that it is possible to claim that it will continue to encourage such false beliefs in the face of contrary knowledge.

But it is not just that the individuals who live in a society based on commodity production are deceived by it regarding the way that it works. The way that it works is itself criticized by Marx. Above all, the 'social character of labour' is made private in actuality. This is not a misperception or false belief, but a contradiction: a discrepancy between what Marx takes to be the intrinsic nature of social labour and the way that it is in fact organized. Capitalism is not just deceptive, but also defective.

11 Morality

The question whether Marx's theory has a moral or ethical dimension is one of the most controversial of all issues surrounding the interpretation of his work, and the difficulty facing interpreters is easily seen. On the one hand, Marx has a number of uncompromisingly negative things to say about morality. Moreover, after 1845 at least, he affirms that his own theory is not a utopian or ethical one but 'real, positive science'. Yet, on the other hand, much of the language that he uses to describe capitalism is plainly condemnatory (for instance, that it is antagonistic, oppressive and exploitative). Does this not represent an inconsistency on Marx's part? Is he not moralizing and rejecting morality at the same time?

This section will present a line of interpretation according to which Marx is not inconsistent. The interpretation depends on a contrast between certain doctrines typical of moral philosophy

(which, it will be argued, Marx rejects) and the rejection of ethical values as such (to which, it will be argued, he is not thereby committed). However, it should be noted that this interpretation is controversial and involves considerable reconstruction of the rather sparse evidence that we have of Marx's views.

It is helpful to start, as Marx himself did, with Hegel's critique of Kant. Both Marx and Hegel share the belief that morality, as embodied in Kant's moral philosophy, is, as they put it, 'abstract' (see HEGEL, G.W.F. §8). There appear to be three interconnected elements compressed into this criticism:

(1) First, morality is alleged to be abstract in the sense that it contains principles expressed in universal form (in Kant's case, the 'categorical imperative' to 'act only according to that maxim which you can, at the same time, will to be a universal law' (see KANTIAN ETHICS)). While such principles may function as a test upon proposed actions, they do not, the argument goes, determine the content of the action to be performed. Thus, the claims of moral philosophy to the contrary, specific content is surreptitiously imported into ethics from the existing institutions or codes of behaviour of the society in question.
(2) Second, morality is abstract to the extent that it takes the form of a mere injunction: an imperative that is addressed to people's 'moral reason', telling them to act in a certain way because that is 'good in itself'. Moral action is detached thereby from other forms of human action and, as a result, moral theory has nothing to say about the conditions under which the forms of behaviour that it commends will be realized in practice.
(3) Finally, morality may be said to be abstract in that it contains an unhistorical understanding of its own status. It presents its principles as if they were the axioms of some timeless moral geometry. Yet, in fact, every system of morality is a way of seeing the world that arises in particular circumstances and responds to definite needs within those circumstances.

Although one or more of these features may be present in the forms of moral philosophy with which we are most familiar, it is not clear that they are a necessary feature of every view that one might call 'moral'. Not all ethical positions have to express themselves as systems of universal principles that we are enjoined to follow because they are good for their own sake. Admittedly, many philosophers would argue that to combine the value commitments characteristic of morality with the meta-level doctrine that such values are, in the end, expressions of interest (Marx's version of (3) above) inevitably undermines, as Nietzsche might have put it, the value of value itself. But it is at least arguable that the two standpoints are compatible. The path from sociological determinism to moral scepticism is not as steep, slippery and remorseless as it is sometimes claimed to be.

If this is conceded, we can draw a distinction between morality in two senses: morality as a quasi-Kantian system of principles (which Marx rejects) and morality as a set of values embodying a conception of what is good for human beings (which he can consistently accept). To present things in this way, however, may seem to give insufficient weight to the vehement hostility which Marx shows towards ideas of justice and rights, in particular. On the interpretation being proposed here, Marx's animus is best understood as aimed at what he sees as the assumptions behind such values, rather than at the fact of their being values as such.

Roughly speaking, we may think of rights as things that permit individuals to act in certain ways, in given circumstances, should they wish to do so, and to be able to claim correlative duties on the part of others. A duty, correspondingly, would require individuals to act in some way, whether they wished to or not. Justice (if we do not think of it simply as a matter of rights and duties) would consist of principles on which benefits and burdens are distributed in cases where interests conflict.

What these values have in common is that they provide a framework which regulates and limits the self-seeking behaviour of individuals. They are values that assume a conflict between (to put it in Kantian terms) 'duty' and 'inclination'. Just as Marx supposes that the categories of bourgeois economics eternalize the forms of bourgeois economic life, so, he believes, discussion of rights (which he denounces in the *Critique of the Gotha Programme* as 'ideological nonsense') eternalizes a situation in which the good of each individual is independent and so can only be advanced at the expense of others. Right, moreover, can only apply a fixed and equal standard to unequal individuals, 'from outside'.

For the liberal, who is concerned to protect the individual's powers of self-direction against the intrusions of others, the attraction of the idea of rights is that it presupposes nothing about individuals' characters and personalities. For Marx, on the other hand, that is just its weakness: rights do nothing to transform human nature. Against this, it is clear that Marx, from the time of the *Paris Manuscripts*, sees social progress as characterized by a form of community in which (as he and Engels put it in the *Communist Manifesto*) 'the free development of each is the condition for the free development of all'. Marx's ethical ideal is one of solidarity in which all advance together.

Hence Marx's reluctance to use the language of justice to condemn capitalism becomes more intelligible. It is not that Marx thinks that exploitation, expropriation, oppression, slavery and misery (a few of the terms he applies to the capitalist system) are *just*. But he is reluctant to use language that would suggest that these are forms of injustice for which 'justice' (in the sense of giving 'each their due') is the final and sufficient remedy.

12 Socialism

It may seem odd, given that Marx devoted his life to the achievement of a socialist society, how brief and unspecific his accounts of it are. One explanation that is often advanced for this apparent neglect is the following. Marx believed, it is said, that thought is limited to its own time. Thus it would have been improper for him, living under capitalism, to try to anticipate the nature of the society that would replace it and to write (as he puts it in the Preface to the Second Edition of *Das Kapital*) 'recipes for the cook-shops of the future'. While this may be part of the reason for Marx's reticence, it cannot alone suffice. For, even if we grant that Marx believed that each stage of society sets a boundary which thought cannot cross (and it is by no means beyond question that he did hold this view in such a strong form) he is also committed to the view that socialism is anticipated within capitalism.

In the Preface to *Zur Kritik der politischen Ökonomie* Marx makes the general claim that new forms of society are always prefigured within the old ones that they replace. 'Mankind', he writes, 'only sets itself such tasks as it is able to solve, since closer examination will always show that the problem itself arises only when the material conditions for its solution are already present or at least in the course of formation'.

Marx describes the process by which capitalism prepares the ground for socialism at the end of the first volume of *Das Kapital*. As the productive forces developed by capitalism grow, he claims, so too does the 'mass of misery, oppression, slavery, degradation, exploitation'. A stage is reached, however, at which the monopoly of capital becomes a 'fetter' on production and 'the centralization of the means of production and the socialization of labour at last reach a point where they become incompatible with their capitalist shell'. At this point, the shell 'bursts asunder', the 'death knell' sounds for capitalism and the 'expropriators are themselves expropriated'.

The first and most obvious difference between capitalism and socialism is that common ownership leads to a quite different pattern of distribution of the products of labour. No longer will the capitalist, in virtue of his ownership of the means of production, be able to exploit the individual producer. In the *Critique of the Gotha Programme* Marx distinguishes two stages of post-capitalist society. In the first, the direct producer receives back from society (after deductions for shared costs and social expenditure) 'what he has given to it as his individual quantum of labour'.

But this, Marx points out, is a principle of distribution that merely rectifies exploitation. It does not remedy the inequalities that arise from contingent differences in natural capacities between individual producers. Later, however, society will move beyond this, Marx claims, and 'the narrow horizon of bourgeois right' will be 'crossed in its entirety'. At this point, the principle upon which society will operate will be: 'From each according to his ability, to each according to his needs!' But socialism is distinguished by more than its principle of distribution. In particular, labour will be organized quite differently from the way that it is organized under capitalism.

One of Marx's few reasonably extensive accounts of the nature of the socialist organization of production is to be found in the section on the fetishism of commodities in *Das Kapital*, as part of a comparison between capitalist and other forms of production. Marx starts with Robinson Crusoe, whose productive activity he describes as 'simple and clear'. For Robinson, Marx says, the organization of production is a purely administrative operation: the end is known, as are the resources available and the techniques by which that end could be attained. Marx then moves from 'Robinson's island, bathed in light', via feudal and patriarchal forms of production, before alighting on: 'a community of free individuals, carrying on their labour with the means of production in common, in which the labour-power of all the different individuals is consciously applied as the combined labour-power of the community'.

Here, Marx says,

> All the characteristics of Robinson's labour are . . . repeated, but with this difference, that they are social, instead of individual . . . The social relations of the individual producers to their labour and to the products of their labour remain here transparently simple, in production as well as in distribution.
>
> (*Das Kapital*)

The idea that labour could be 'consciously applied' in a complex modern society – resources and needs coordinated, efficient techniques adopted, innovation managed – with the same 'transparent simplicity' as an individual allocating his time to different tasks on a desert island is astonishingly implausible. And, even if it were not

so, the question would still arise how that 'common and rational plan' (as Marx terms it elsewhere) would relate to the individuals whose task it was to carry it out. Would it not, from their point of view, be no less of an 'external' imperative to be followed than the dictates of the market that govern their labour under capitalism? Arguably, the idea that society under socialism would be spontaneously unified like one great, self-transparent super-individual represents an unacknowledged hangover in Marx's mature thought from Hegel's doctrine of *Geist*. However that may be, the presence of this doctrine goes a long way towards explaining why Marx had so little to say about the problems of socialist economic organization: he simply failed to see the difficulty. Few theoretical omissions, surely, have ever had more disastrous historical consequences.

MARXISM, WESTERN

Western Marxism is used here as an umbrella term for the various schools of Marxist thought that have flourished in Western Europe since Marx's death in 1883. It is sometimes used more narrowly to refer to those Marxist philosophers whose thinking was influenced by the Hegelian idea of dialectics and who focused their attention on the cultural as opposed to the economic aspects of capitalism. In the broader sense, Western Marxism does not denote any specific doctrine, but indicates a range of concerns that have exercised Marxist philosophers in advanced capitalist societies. These concerns primarily have been of three kinds: (1) *epistemological* – what would justify the claim that Marxist social theory and, in particular, the materialist conception of history are true?; (2) *ethical* – does the Marxist critique of capitalism require ethical foundations, and if so, where are these to be discovered; and (3) *practical* – if the economic collapse of capitalism can no longer be regarded as inevitable, who are the agents who can be expected to carry through a socialist transformation?

In relation to the first issue, the main debate has been between those who, following Engels, adhere to 'scientific socialism' (that is, the view that Marxism is a science in the same sense as the natural sciences), and those who claim that Marxist epistemology relies on a form of dialectics quite distinct from the methods of natural science. The most prominent exponent of this second view was the Hungarian philosopher Georg Lukács, who drew upon the dialectical method of Hegel, with class consciousness replacing *Geist* (Spirit) as the vehicle of dialectical reason. Thus, for Lukács the truth of historical materialism and the goodness of communism were both established dialectically, through the class consciousness of the revolutionary proletariat. Lukács' advocacy of dialectics was later taken up and developed by the philosophers of the Frankfurt School.

In relation to the second issue, early dissenters from the orthodox Marxism of Engels like Eduard Bernstein looked outside Marxism itself, and especially to the philosophy of Kant, for the ethical principles that would justify socialism. The position changed somewhat with the rediscovery of the young Marx's *Paris Manuscripts* (1844) from which later Marxists, and in particular those associated with the Frankfurt School, were able to extract a humanistic ethics centred on the notion of alienation.

In relation to the third issue, most Western Marxists continued to look to the proletariat as the agency of revolutionary change, often distinguishing, as did Lukács, between the true consciousness of that class and the false consciousness that reflected the distorting effects of bourgeois ideology. But in the case of the Frankfurt Marxists, the critical theory that pointed the way to a liberated human future was detached from any specific agency and treated merely as critique. The most original contribution was made by the Italian Marxist Antonio Gramsci, who argued that the working class must use the power of its ideas to establish hegemony over the other classes in bourgeois society, who would then join the proletariat in overthrowing capitalism.

The disintegration of Western Marxism began in the 1960s when the French philosopher Louis Althusser attacked both the use of Hegelian dialectics by Marxists and the various forms of Marxist humanism. Althusser insisted that Marxism was a science which required no ethical foundations. His

critique was informed by a conviction that human subjectivity, together with the philosophical problems generated by subject–object dualism, are illusions.

Althusserian Marxism became fashionable in English-speaking universities, but its cavalier and paradoxical style also led, by reaction, to the rise of analytic Marxism in the late 1970s. Analytic Marxists returned to interrogating Marx's texts in more conventional ways, using the methods of analytic philosophy and contemporary social science to reformulate them to withstand academic scrutiny by non-Marxists. A tendency rather than a movement, analytic Marxism perhaps marks the final stage of a process that began with Lukács, that of turning Marxism into a purely academic study remote from politics.

MARXIST PHILOSOPHY, RUSSIAN AND SOVIET

The history of Russian Marxism involves a dramatic interplay of philosophy and politics. Though Marx's ideas were taken up selectively by Russian populists in the 1870s, the first thoroughgoing Russian Marxist was G.V. Plekhanov, whose vision of philosophy became the orthodoxy among Russian communists. Inspired by Engels, Plekhanov argued that Marxist philosophy is a form of 'dialectical materialism' (Plekhanov's coinage). Following Hegel, Marxism focuses on phenomena in their interaction and development, which it explains by appeal to dialectical principles (for instance, the law of the transformation of quantity into quality). Unlike Hegel's idealism, however, Marxism explains all phenomena in material terms (for Marxists, the 'material' includes economic forces and relations). Dialectical materialism was argued to be the basis of Marx's vision of history according to which historical development is the outcome of changes in the force of production.

In 1903, Plekhanov's orthodoxy was challenged by a significant revisionist school: Russian empiriocriticism. Inspired by Mach's positivism, A.A. Bogdanov and others argued that reality is socially organized experience, a view they took to suit Marx's insistence that objects be understood in their relation to human *activity.* Empiriocriticism was associated with the Bolsheviks until 1909, when Lenin moved to condemn Bogdanov's position as a species of idealism repugnant to both Marxism and common sense. Lenin endorsed dialectical materialism, which thereafter was deemed the philosophical worldview of the Bolsheviks.

After the Revolution of 1917, Soviet philosophers were soon divided in a bitter controversy between 'mechanists' and 'dialecticians'. The former argued that philosophy must be subordinate to science. In contrast, the Hegelian 'dialecticians', led by A.M. Deborin, insisted that philosophy is needed to explain the very possibility of scientific knowledge. The debate was soon deadlocked, and in 1929 the dialecticians used their institutional might to condemn mechanism as a heresy. The following year, the dialecticians were themselves routed by a group of young activists sponsored by the Communist Party. Denouncing Deborin and his followers as 'Menshevizing idealists', they proclaimed that Marxist philosophy had now entered its 'Leninist stage' and invoked Lenin's idea of the *partiinost'* ('partyness') of philosophy to license the criticism of theories on entirely political grounds. Philosophy became a weapon in the class war.

In 1938, Marxist-Leninist philosophy was simplistically codified in the fourth chapter of the *Istoriia kommunisticheskoi partii sovetskogo soiuza (Bol'sheviki). Kraatkii kurs* (History of the Communist Party of the Soviet Union (Bolsheviks). Short Course). The chapter, apparently written by Stalin himself, was declared the height of wisdom, and Soviet philosophers dared not transcend its limited horizons. The 'new philosophical leadership' devoted itself to glorifying the Party and its General Secretary. The ideological climate grew even worse in the post-war years when A.A. Zhdanov's campaign against 'cosmopolitanism' created a wave of Russian chauvinism in which scholars sympathetic to Western thought were persecuted. The Party also meddled in the scientific, sponsoring T.D. Lysenko's bogus genetics, while encouraging criticism of quantum mechanics, relativity theory and cybernetics as inconsistent with dialectical materialism.

The Khrushchev 'thaw' brought a renaissance in Soviet Marxism, when a new generation of young philosophers began a critical re-reading of Marx's texts. Marx's so-called 'method of ascent from the abstract to the concrete' was developed, by E.V. Il'enkov and others, into an anti-empiricist epistemology. There were also important studies of consciousness and 'the ideal' by Il'enkov and M.K. Mamardashvili, the former propounding a vision of the social origins of the mind that recalls the cultural-historical psychology developed by L.S. Vygotskii in the 1930s.

However, the thaw was short-lived. The philosophical establishment, still populated by the Stalinist old guard, continued to exercise a stifling influence. Although the late 1960s and 1970s saw heartfelt debates in many areas, particularly about the biological basis of the mind and the nature of value (moral philosophy had been hitherto

neglected), the energy of the early 1960s was lacking. Marxism-Leninism still dictated the terms of debate and knowledge of Western philosophers remained relatively limited.

In the mid-1980s, Gorbachev's reforms initiated significant changes. Marxism-Leninism was no longer a required subject in all institutions of higher education; indeed, the term was soon dropped altogether. Discussions of democracy and the rule of law were conducted in the journals, and writings by Western and Russian émigré philosophers were published. Influential philosophers such as I.T. Frolov, then editor of *Pravda*, called for a renewal of humanistic Marxism. The reforms, however, came too late. The numerous discussions of the fate of Marxism at this time reveal an intellectual culture in crisis. While many maintained that Marx's theories were not responsible for the failings of the USSR, others declared the bankruptcy of Marxist ideas and called for an end to the Russian Marxist tradition. Following the collapse of the Soviet Union in 1991, it seems their wish has been fulfilled.

MASS TERMS

Mass terms are words and phrases such as 'water', 'wood' and 'white wallpaper'. They are contrasted with count terms such as 'woman', 'word' and 'wild wildebeest'. Intuitively, mass terms refer to 'stuff'; count terms refer to 'objects'. Mass terms allow for measurement ('three kilos of wood', 'much water'); count terms allow for counting, quantifying and individuating ('three women', 'each word', 'that wildebeest over there').

Philosophical problems associated with mass terms include; (1) distinguishing mass from count terms, (2) describing the semantics of sentences employing mass terms, and (3) explicating the ontology presupposed by our use of mass versus count terms. Associated with these philosophical issues – especially the third – are the meta-philosophical issues concerning the extent to which any investigation into the linguistic practices of speakers of a language can be used as evidence for how those speakers view 'reality'.

MATERIALISM

Introduction

Materialism is a set of related theories which hold that all entities and processes are composed of – or are reducible to – matter, material forces or physical processes. All events and facts are explainable, actually or in principle, in terms of body, material objects or dynamic material changes or movements. In general, the metaphysical theory of materialism entails the denial of the reality of spiritual beings, consciousness and mental or psychic states or processes, as ontologically distinct from, or independent of, material changes or processes. Since it denies the existence of spiritual beings or forces, materialism typically is allied with atheism or agnosticism.

The forms of materialism extend from the ancient Greek atomistic materialism through eighteenth- and nineteenth-century scientifically based theories, to recent sophisticated defences of various types of materialism.

1 Materialism

Materialism is the general theory that the ultimate constituents of reality are material or physical bodies, elements or processes. It is a form of monism in that it holds that everything in existence is reducible to what is material or physical in nature. It is opposed to dualistic theories which claim that body and mind are distinct, and directly antithetical to a philosophical idealism that denies the existence of matter. It is hostile to abstract objects, if these are viewed as more than just a manner of speaking (see Abstract objects). An implication of materialism is that the diverse qualitative experiences we have are ultimately reducible to quantitative changes in objects or in our physiological functioning. All the properties of things, including persons, are reducible to properties of matter. Although the terms referring to psychic states such as intention, belief, desire and consciousness itself have a different sense and use than terms referring to material events, a consistent materialist would deny that mentalistic terms have reference to anything other than physical events or physiological changes in our brains. The enormous advances in the sciences have contributed storehouses of empirical data that are often used to support materialism. Many philosophers have been

attracted to materialism both because of its reductive simplicity and its association with scientific knowledge.

2 Ancient Greek atomism

Although LEUCIPPUS is credited with inventing the atomic theory of matter in the fifth century BC, it was DEMOCRITUS (fourth century BC) who developed a systematic theory of atomistic materialism. This theory states that matter is composed of separate and minute elements that are 'uncuttable' (*atoma*), that these elements move in empty space or the 'void'. Atoms differ only in shape and volume, and all change occurs by the transfer through direct contact of movement from atoms in motion. These elementary entities are lacking in secondary qualities and are indestructible. Democritus held that things are hot or cold, sweet or bitter, or have different colours 'by convention'. In reality, 'there are atoms and the void'.

The essentials of early atomism were retained in Epicurus' physics, with the exception that Epicurus ascribed freedom to atoms in their movement through space. Epicurean materialism is lucidly expressed in the philosophic poem by LUCRETIUS, *De rerum natura* (On the Nature of Things), in the first century BC. This popularization of Epicurean thought did much to keep alive both atomistic materialism and what is already recognizable as a naturalistic understanding of humans and world (see EPICUREANISM).

3 Modern materialism

During the first half of the seventeenth century the atomistic materialism of the Greco-Roman period was revived in a paradoxical way by Pierre GASSENDI. He appreciated the scientific interpretation of nature and the methods of science but, at the same time, preserved the Christian idea of the immortality of the soul and conceived of God as the creator of the atoms. The English philosopher Thomas HOBBES presented a systematic theory of nature and human nature that was largely, though not completely, materialistic. Apart from attributing 'drive' or *conatus* to human action and sensation, Hobbes virtually banished the concept of 'incorporeal substance'. In theory and sentiment Hobbes was a materialist thinker, although not a consistent one. The early eighteenth century saw the publication of the first of many works that defended a materialistic and mechanistic interpretation of mankind's nature on the basis of physiological theory. In *L'Homme machine* (1748) Julien de LA METTRIE, a philosophical physician, described human beings as self-moving mechanisms and sought a neurological basis for mental activity. An advance on previous attempts to develop a systematic materialism is Paul H.D. d'Holbach's 1770 *Système de la nature* (The System of Nature). Here, a consistent naturalistic materialism is expounded in that cognitive and emotive states are reduced to internal material 'modifications of the brain'. Though not calling it such, d'Holbach presents a form of physiological determinism.

With the rapid growth of the sciences, the astronomical discoveries of COPERNICUS, the theories of GALILEO, and the systematic conception of nature in the physical theory of Isaac NEWTON, naturalistic interpretations of a variety of phenomena became more and more prevalent. This scientifically founded picture of reality lent greater plausibility to the principles of materialistic theory. The astronomer and mathematician Pierre Laplace (1749–1827) produced a sophisticated astronomical theory which, he thought, illustrated that a supermind, knowing all the states and conditions of every existing entity, could predict the total state of the cosmos in the next moment. When Napoleon I was shown a copy of Laplace's work, he is supposed to have commented on the absence of any mention of God. Laplace replied, 'I have no need of that hypothesis'. Laplace's mechanistic materialism became, in the hands of many thinkers, the definitive explanatory principle of all events.

The formulation of the biological theory of evolution by means of natural selection by Charles DARWIN virtually eliminated teleological explanations of biological phenomena and thereby buttressed material and physical interpretations of organic development. With the advances in chemistry achieved by Lavoisier (1743–94) in France and John Dalton (1766–1844) in England, the reductive analysis of natural phenomena to chemical substances, elements and processes bolstered the empirical, naturalistic and materialistic interpretations of phenomena. During the nineteenth century many philosophical thinkers sought to build theories on the foundation of scientific facts, principles or laws. The historical materialism developed by Marx and Engels sought to formulate laws of social, economic and historical development, but did not defend metaphysical materialism (see DIALECTICAL MATERIALISM). The general appeal of materialism in the nineteenth century is shown by the popularity of the 1855 work by Ludwig Büchner, *Kraft und Stoff* (Force and Matter), which passed through sixteen editions. Although philosophically crude, it is an accessible compendium of popular materialism. In 1852, Jacob Moleschott had defended the reduction of force to matter, the doctrine of the conservation of matter, and a species of objective relativism in *Der Kreislauf des Lebens*

(The Cycle of Life). Following the ill-chosen analogy between the brain and thought and the digestive system in Jean Cabanis' *Rapports due physique et du moral de l'homme* (Relations of the Physical and the Mental in Man) (1802), Karl Vogt proclaimed that the brain 'secretes' thought the way the liver secretes bile. Despite such excursions into 'vulgar materialism', the nineteenth century became a period of intense debate for scientists and philosophers alike in regard to the limits of scientific knowledge and the epistemological problems of metaphysical materialism. This was fuelled by a Neo-Kantian movement which, particularly in *Geschichte des Materialismus* (History of Materialism) (1865) by F.A. LANGE, held that materialism is a useful methodological principle in science, but questionable as a reductionist metaphysics. The concepts and postulates of science are theoretical entities or conventional notions formed by the mind. Their usefulness does not, according to Lange, warrant their role as bases for materialism.

4 Recent materialism

In the twentieth century, physicalism has emerged out of positivism. Physicalism restricts meaningful statements to physical bodies or processes that are verifiable or in principle verifiable. It is an empirical hypothesis that is subject to revision and, hence, lacks the dogmatic stance of classical materialism. Herbert Feigl defended physicalism in the USA and consistently held that mental states are brain states and that mental terms have the same referent as physical terms (Feigl 1958). The twentieth century has witnessed many materialist theories of the mental, and much debate surrounding them (see BEHAVIOURISM, ANALYTIC; FUNCTIONALISM; MATERIALISM IN THE PHILOSOPHY OF MIND; MIND, IDENTITY THEORY OF).

In the field of artificial intelligence, the mind is held to be analogous to computers in so far as it functions as an information-processing entity. Daniel DENNETT has, in a qualified way, argued that information-processing machines are valid models of the mind. In addition to the scientifically informed arguments for various forms of materialism, including nonreductive materialism, the twentieth-century conception of matter as composed of electrons, protons and other subatomic particles has spawned a rich speculative literature that effectively undermines previous forms of materialism. What the late US philosopher of science, Norwood Hanson, called the 'dematerialization' of matter, raises questions concerning what 'materialism' means in terms of the theories of microphysics. Many of the arguments that sustained earlier forms of materialism (including the assumption of causality as universal in nature) have been put in question. The confluence of contemporary theories about the structure and function of the mind and the nature of matter have introduced a complexity of detail and an array of paradoxical claims that make contemporary materialism a welter of intriguing, but conflicting and perplexing, theoretical elements.

MATERIALISM, DIALECTICAL

See DIALECTICAL MATERIALISM

MATERIALISM IN THE PHILOSOPHY OF MIND

Materialism – which, for almost all purposes, is the same as physicalism – is the theory that everything that exists is material. Natural science shows that most things are intelligible in material terms, but mind presents problems in at least two ways. The first is consciousness, as found in the 'raw feel' of subjective experience. The second is the intentionality of thought, which is the property of *being about* something beyond itself; 'aboutness' seems not to be a physical relation in the ordinary sense.

There have been three ways of approaching these problems. The hardest is eliminativism, according to which there are no 'raw feels', no intentionality and, in general, no mental states: the mind and all its furniture are part of an outdated science that we now see to be false. Next is reductionism, which seeks to give an account of our experience and of intentionality in terms which are acceptable to a physical science: this means, in practice, analysing the mind in terms of its role in producing behaviour. Finally, the materialist may accept the reality and irreducibility of mind, but claim that it depends on matter in such an intimate way – more intimate than mere causal dependence – that materialism is not threatened by the irreducibility of mind. The first two approaches can be called 'hard materialism', the third 'soft materialism'.

The problem for eliminativism is that we find it difficult to credit that any belief that we think and feel is a theoretical speculation. Reductionism's main difficulty is that there seems to be more to consciousness than its contribution to behaviour: a robotic machine could behave as we do without thinking or feeling. The soft materialist has to explain supervenience in a way that makes the mind not epiphenomenal without falling into the problems of interactionism.

HOWARD ROBINSON

MATERIALISM, INDIAN SCHOOL OF

'Materialism' stands here for the Sanskrit term Lokāyata, the most common designation for the materialistic school of classical Indian philosophy. However, at the outset 'materialism' and 'Lokāyata' were not equivalent: early materialistic doctrines were not associated with Lokāyata, and early Lokāyata was neither materialistic nor even a philosophical school.

Classical Lokāyata stands apart from all other Indian philosophical traditions due to its denial of ethical and metaphysical doctrines such as karmic retribution, life after death, and liberation. Its ontology, tailored to support this challenge, allows only four material elements and their various combinations. Further support comes from Lokāyata epistemology: the validity of inference and Scriptures is denied and perception is held to be the only means of valid cognition. As offshoots, a fully fledged scepticism and a theory of limited validity of inference developed in response to criticism by other philosophers. Consistent with Lokāyata ontology and epistemology, its ethics centres on the criticism of all religious and moral ideals which presuppose invisible agents and an afterlife. Hostile sources depict its followers as promulgating unrestricted hedonism.

MATHEMATICS, FOUNDATIONS OF

Introduction

Conceived of philosophically, the foundations of mathematics concern various metaphysical and epistemological problems raised by mathematical practice, its results and applications. Most of these problems are of ancient vintage; two, in particular, have been of perennial concern. These are its richness of content and its necessity. Important too, though not so prominent in the history of the subject, is the problem of application, or how to account for the fact that mathematics has given rise to such an extensive, important and varied body of applications in other disciplines.

The Greeks struggled with these questions. So, too, did various medieval and modern thinkers. The ideas of many of these continue to influence foundational thinking to the present day.

During the nineteenth and twentieth centuries, however, the most influential ideas have been those of Kant. In one way or another and to a greater or lesser extent, the main currents of foundational thinking during this period – the most active and fertile period in the entire history of the subject – are nearly all attempts to reconcile Kant's foundational ideas with various later developments in mathematics and logic.

These developments include, chiefly, the nineteenth-century discovery of non-Euclidean geometries, the vigorous development of mathematical logic, the development of rigorous axiomatizations of geometry, the arithmetization of analysis and the discovery (by Dedekind and Peano) of an axiomatization of arithmetic. The first is perhaps the most important. It led to widespread acceptance of the idea that space was not merely a Kantian 'form' of intuition, but had an independence from our intellect that made it different in kind from arithmetic. This asymmetry between geometry and arithmetic became a major premise of more than one of the main 'isms' of twentieth-century philosophy of mathematics. The intuitionists retained Kant's conception of arithmetic and took the same view of that part of geometry which could be reduced to arithmetic. The logicists maintained arithmetic to be 'analytic' but differed over their view of geometry. Hilbert's formalist view endorsed a greater part of Kant's conception.

The second development carried logic to a point well beyond where it had been in Kant's day and suggested that his views on the nature of mathematics were in part due to the relatively impoverished state of his logic. The third indicated that geometry could be completely formalized and that intuition was therefore not needed for the sake of conducting inferences within proofs. The fourth and fifth, finally, provided for the codification of a large part of classical mathematics – namely analysis and its neighbours – within a single axiomatic system – namely (second-order) arithmetic. This confirmed the views of those (for example, the intuitionists and the logicists) who believed that arithmetic had a special centrality within human thinking. It also provided a clear reductive target for such later anti-Kantian enterprises as Russell's logicism.

The major movements in the philosophy of mathematics during this period all drew strength from post-Kantian developments in mathematics and logic. Each, however, also encountered serious difficulties soon after gaining initial momentum. Frege's logicism was defeated by Russell's paradox; Russell's logicism, in turn, made use of such questionable (from a logicist standpoint) items as the axioms of infinity and reduction. Both logicism and Hilbert's formalist programme came under heavy attack from Gödel's incompleteness theorems. And finally, intuitionism suffered from its inability to produce a body of mathematics comparable in richness to classical mathematics.

Despite the failure of these non-Kantian programmes, however, movement away from Kant continued in the mid- and late twentieth century. From the 1930s on this has been driven mainly by a revival of empiricist and naturalist ideas in philosophy, prominent in the writings of both the logical empiricists and the later influential work of Quine, Putnam and Benacerraf. This continues as perhaps the major force shaping work in the philosophy of mathematics.

1 Kant's views; reactions

The '*Problematik*' that Kant established for the epistemology of pure mathematics focused on the reconciliation of two apparently incompatible features of pure mathematics: (1) the problem of necessity, or how to explain the apparent fact that mathematical statements (for example, statements such that 1+1=2 or that the sum of the interior angles of a Euclidean triangle is equal to two right angles) should appear to be not only true but necessarily true and independent of empirical evidence; and (2) the problem of cognitive richness, or how to account for the fact that pure mathematics should yield subjects as rich and deep in content and method, as robust in growth and as replete with surprising discoveries as the history of mathematics demonstrates.

In mathematics, Kant said, we find a 'great and established branch of knowledge' – a cognitive domain so 'wonderfully large' and with promise of such 'unlimited future extension' that it would appear to arise from sources other than those of pure unaided (human) reason (*Prolegomena*: §§6, 7). At the same time, it carries with it a certainty or necessity that is typical of judgments of pure reason. The problem, then, is to explain these apparently conflicting characteristics. Kant's explanation was that mathematical knowledge arises from certain standing conditions or 'forms' which shape our experience of space and time – forms which, though they are part of the innate cognitive apparatus that we bring to experience, none the less shape our experience in a way that goes beyond mere logical processing.

To elaborate this hypothesis, Kant sorted judgments/propositions in two different ways: first, according to whether they required appeal to sensory experience for their justification; and, second, according to whether their predicate concepts were 'contained in' their subject concepts. A judgment or proposition was 'a priori' if it could be justified without appeal to sensory content. If not, it was 'a posteriori'. It was 'analytic' if the very act of *thinking* the subject concept contained, as a constituent part, the *thinking* of the predicate concept. If not, it was either false or 'synthetic'. In synthetic a priori judgment – the type of judgment Kant regarded as characteristic of mathematics – the predicate concept was thought not through the mere *thinking* of the subject concept, but through its 'construction in intuition'. He took a similar view of mathematical inference, believing it to involve an intuition that goes beyond the mere logical connection of premises and conclusions (*Critique of Pure Reason*: A713–19/B741–7).

Kant erected his mathematical epistemology upon these distinctions and, famously, maintained that mathematical judgment and inference is synthetic a priori in character. In this way, he intended to account for both the necessity and cognitive richness of mathematics, its necessity reflecting its a priority, its cognitive richness its syntheticity.

Kant applied this basic outlook to both arithmetic and geometry (and also to pure mechanics). He did not regard them as entirely identical, however, since he saw them as resting on different a priori intuitions. Neither did he see them as possessing precisely the same universality (*Critique*: A163–5, 170–1, 717, 734/B204–6, 212, 745, 762). None the less, he regarded their similarities as more important than their differences and therefore took them to be of essentially the same epistemic type – namely, synthetic a priori. In the end, it was this inclusion of geometry and arithmetic within the same basic epistemic type rather than his more central claim concerning the *existence* of synthetic a priori knowledge that gave rise to the sternest challenges to his views.

In the decades following the publication of the first *Critique*, the principal source of concern regarding its views was the growing evidence for and eventual discovery of non-Euclidean geometries. This led many to question whether geometry and arithmetic are of the same basic epistemic character.

The serious possibility of non-Euclidean geometries went back to the work of Lambert and others in the eighteenth century. Building on this work, some – in particular, Gauss (Letters to Olbers and Bessel) – stated their opposition to Kant's views even before the actual discovery of non-Euclidean geometries by Bolyai and Lobachevskii in the 1820s. Gauss' reasoning was essentially this: number seems to be purely a product of the intellect and, so, something of which we can have purely a priori knowledge. Space, on the other hand, seems to have a reality external to our minds that prohibits a purely a priori knowledge of it. Arithmetic and geometry are therefore not on an epistemological par with one another.

This reasoning became a potent force shaping nineteenth- and twentieth-century foundational thinking. Another such force was the dramatic development of logic and the axiomatic method in the mid- to late nineteenth century and early twentieth century. This included the introduction of algebraic methods by Boole and De Morgan, the improved treatment of relations by Peirce, Schröder and Peano, the replacement of the subject–predicate conception of propositional form with Frege's more fecund functional conception, and the advances in axiomatization and formalization brought about by the work of Frege, Pasch, Peano, Hilbert and (especially) Whitehead and Russell.

Certain developments in mathematics proper also exerted an influence. Chief among these were the arithmetization of analysis by Weierstrass, Dedekind and others, and the axiomatization of arithmetic by Peano and Dedekind. Of somewhat lesser importance, though still significant for their effects on Hilbert's thinking, were Einstein's relativistic ideas in physics.

2 Intuitionism

A variety of views concerning the asymmetry of geometry and arithmetic emerged in the late nineteenth and early twentieth centuries. That of the early intuitionists Brouwer and Weyl retained Kant's synthetic a priori conception of arithmetic.

They responded to the discovery of non-Euclidean geometries, however, by denying the a priori status of that part of geometry that could not be reduced to arithmetic by such means as Descartes' calculus of coordinates. They retained, none the less, a type of a priori intuition of time as the basis for arithmetical knowledge. They also emphasized the synthetic character of arithmetical judgment and inference, and sharply distinguished them from logical judgment and inference.

Brouwer described his intuition of time as consciousness of change *per se* – the human subject's primordial inner awareness of the 'falling apart' of a life-moment into a part that is passing away and a part that is becoming. He believed that, via a process of abstraction, one could pass from this basal intuition of time to a concept of 'bare two-oneness', and from this concept to, first, the finite ordinals, then the transfinite ordinals and, finally, the linear continuum. In this way, parts of classical arithmetic, analysis and set theory could be recaptured intuitionistically.

Brouwer thus modified Kant's intuitional basis for mathematics. He also modified his conception of knowledge of existence. Kant believed that humans could obtain knowledge of existence only through sensible intuition. Only this, he believed, had the type of involuntariness and objectivity that assures us that belief in an object is not a mere compulsion or idiosyncrasy of our subjective selves. Like the post-Kantian romantic idealists, however, Brouwer (and Weyl, too) believed as well in knowledge of existence via a kind of 'intellectual intuition' – an intuition carried by a purely internal type of mental construction.

The early intuitionists (especially Brouwer and Poincaré) remained Kantian in their conception of mathematical reasoning and took it to be essentially different in character from 'discursive' or logical reasoning. Brouwer believed logical reasoning to mark not patterns in mathematical thinking itself but only patterns in its linguistic representation. It was therefore not indicative of the inferential structure of mathematical thinking itself and had no place within genuine mathematical reasoning *per se*. This was essentially the idea expressed in Brouwer's so-called 'First Act of Intuitionism'.

Thus the early intuitionists (especially Brouwer and Weyl and, to some extent, Poincaré) discarded Kant's view of geometry, revised his conception of arithmetic and existence claims, and preserved his basic stance on the nature of mathematical reasoning and its relationship to logical reasoning. Later intuitionists (for example, Heyting and Dummett) did not keep to this plan. They rejected Brouwer's view of the divide between logical and mathematical reasoning and made a significant place for logic in their accounts of mathematical reasoning. Some of them (Dummett and his 'anti-realist' followers) even went so far as to make the question 'What is the logic of mathematical reasoning?' central to their philosophy of mathematics (see §5).

3 Logicism

The view of the logicist Frege (and, to some extent, of Dedekind) accepted Kant's synthetic a priori conception of geometry but maintained arithmetic to be analytic. Russell, another logicist, rejected Kant's views of both geometry and arithmetic (and also of pure mechanics) and maintained the analyticity of both. (See Logicism.)

Frege's logicism differed sharply from intuitionism. First, it differed in the place in mathematical reasoning it assigned to logic. Frege (*Die Grundlagen der Arithmetik*: preface) maintained that reasoning is essentially the same everywhere and that even an inference pattern such as that of mathematical induction, which appears to be peculiar to mathematics, is, at bottom, purely logical. Second, it differed in its conception of geometry. Like the early intuitionists, Frege regarded the discovery of non-Euclidean geometries as revealing an important asymmetry between arithmetic and geometry. Unlike them, however, he did not see this as grounds for rejecting Kant's synthetic a priori conception of geometry (*Begriffsschrift*; *Die Grundlagen*), but rather as indicating a fundamental difference between geometry and arithmetic. Frege believed the fundamental concept of arithmetic – magnitude – to be both too pervasive and too abstract to be the product of Kantian intuition (1874: 50). It figured in *every* kind of thinking and so must, he reasoned, have a basis in thought deeper than that of intuition. It must have its basis in the very core of rational thought itself; the laws of logic.

The problem was to account for the cognitive richness of arithmetic on such a view. How could the 'great tree of the science of number' (*Die Grundlagen*: §16) have its roots in bare logical or analytical 'identities'? Frege responded by offering new accounts of both the objectivity and the informativeness of arithmetic. The former he attributed to its subject matter – the so-called 'logical objects' (§§26, 27, 105). The latter he derived from a new theory of content which allowed concepts to contain (tacit) content that was not needed for their grasp. On this view, analytic judgments could have content that was not required for the mere understanding of the concepts contained in them. Consequently, they could yield more than knowledge of transparent logical identities (§§64–6, 70, 88, 91).

Unlike Kant, then, Frege maintained an important epistemic asymmetry between geometry and arithmetic – an asymmetry based upon his belief that arithmetic is more basic to human rational thought than is geometry. In addition, he departed from Kant in maintaining a realistic conception of arithmetic knowledge despite its analytic character. He saw it as being about a class of objects – so-called 'logical objects' – that are external but intimately related to the mind and therefore not the mere expression of standing traits of human cognition. The differences between arithmetical and geometric necessity were to be accounted for by separating the relationship the mind has to the objects of arithmetic from that which it has to the objects of geometry.

Russell's logicism differed from Frege's. Perhaps most importantly, Russell did not regard the existence of non-Euclidean geometries as evidence of an epistemological asymmetry between geometry and arithmetic. Rather, he saw the 'arithmetization' of geometry and other areas of mathematics as evidence of an epistemological symmetry between arithmetic and the rest of mathematics. Russell thus extended his logicism to the whole of mathematics. The basic components of his logicism were a general methodological ideal of pursuing each science to its greatest level of generality, and a conception of the greatest level of generality in mathematics as lying at that point where all its theorems are of the form '*p* implies *q*', all their constants are logical constants and all their variables of unrestricted range. Theorems of this sort, Russell maintained, would rightly be regarded as logical truths.

Russell's logicism was thus motivated by a view of mathematics which saw it as the science of the most general formal truths; a science whose indefinables are those constants of rational thought (the so-called logical constants) that have the most ubiquitous application, and whose indemonstrables are those propositions that set out the basic properties of these indefinables (Russell 1903: 8). In his opinion, such a view provided the only precise description of what philosophers have had in mind when they have described mathematics as a necessary or a priori science.

Russell thus accounted for the necessity of mathematics by pointing to its logical character. He accounted for its richness principally by invoking a new definition of syntheticity that allowed all but the most trivial logical truths and inferences to be counted as informative or synthetic. Mathematical truths would thus be logical truths, but they would not, for all that, be analytic truths. Similarly for inferences. An inference would count as synthetic so long as its conclusion was a different proposition from its premises. Cognitive richness was conceived primarily as the production of new propositions from old, and, on Russell's conception (supposing the criterion of propositional identity to be sufficiently strict), even purely logical inference could produce a bounty of new knowledge from old.

Russell was thus able to account for both the necessity and the cognitive richness of mathematics while making mathematics part of logic. What had kept previous generations of thinkers and, in particular, Kant from recognizing the possibilities of such a view was the relatively impoverished state of logic before the end of the nineteenth century. The new logic, with its robust stock of new forms, its functional conception of the proposition and the ensuing fuller axiomatization of mathematics which it made possible, changed all this forever and provided for the final refutation of Kant. Such, at any rate, was Russell's position.

4 Hilbert's formalism

Hilbert accepted the synthetic a priori character of (much of) arithmetic and geometry, but rejected Kant's account of the supposed intuitions upon which they rest (see HILBERT'S PROGRAMME AND FORMALISM). Overall, Hilbert's position was more complicated in its relationship to Kant's epistemology than were those of the intuitionists and logicists. Like Russell, he rejected Kant's specifically mathematical epistemology – in particular, his conception of the nature and origins of its a priori character. Like Russell, too, he rejected the common post-Kantian belief in the epistemological asymmetry of arithmetic and geometry. Hilbert was, however, unique among those mentioned here in endorsing the framework of Kant's general critical epistemology and making it a central feature of his mathematical epistemology. Specifically, he adopted Kant's distinction between the faculty of the understanding and the faculty of reason as the guide for his pivotal distinction between the so-called 'real' and 'ideal' portions of classical mathematics.

Hilbert took 'real' mathematics to be ultimately concerned with the shapes or forms (*Gestalten*) of concrete signs or figures, given in intuition and comprising a type of 'immediate experience prior to all thought' *On the Infinite* 1926; *Foundations of Mathematics* 1928. Hilbert proposed this basic intuition of shape as a replacement for Kant's two a priori intuitions of space and time. Like Kant's a priori intuitions, however, Hilbert, too regarded his finitary intuition as an 'irremissible pre-condition' of all mathematical (indeed, all scientific) judgment and the ultimate source of all genuine a priori knowledge 'Naturkennen und Logik' 1930.

The genuine judgments of real mathematics were the judgments of which our mathematical knowledge was constituted. The pseudo-judgments of ideal mathematics, on the other hand, functioned like Kant's ideas of reason. They neither described things present in the world nor constituted a foundation for our judgments concerning such things. Rather, they played a purely regulative role of guiding the efficient and orderly development of our real knowledge.

Hilbert did not, therefore, affirm the necessity of either arithmetic or geometry in any simple, straightforward way. Rather, he distinguished two types of necessity operating within both. One, pertaining to the judgments of real mathematics, consisted in the (presumed) fact that the apprehension of certain elementary spatial and combinatorial features of simple concrete objects is a pre-condition of all scientific thought. The other, pertaining to the ideal parts of mathematics, had a kind of psychological necessity, a necessity borne of the manner in which our minds inevitably or best regulate the development of our real knowledge.

This conception of the necessity of mathematics was different from both Kant's and those of the logicists and intuitionists. So, too, was Hilbert's view of the cognitive richness of mathematics, which he attributed both to the objective richness of the shapes and combinatorial features of concrete signs and to the richness of our imaginations in 'creating' complementary ideal objects.

In its overall structure, Hilbert's mathematical epistemology thus resembled Kant's *general* critical epistemology. This included his so-called 'consistency' requirement (that is, the requirement that ideal reasoning not prove anything contrary to that which may be established by real means), which resembled Kant's demand that the faculty of reason not produce any judgment of the understanding that could not in principle be obtained solely from the understanding (*Critique*: A328/B385).

5 Modifications

During the first four decades of the twentieth century, each of the post-Kantian programmes outlined above came under attack. Frege's logicism was challenged by Russell's paradox. Russell's logicism encountered difficulties concerning its use of certain existence axioms (namely his axioms of reducibility and infinity) which did not appear to be laws of *logic*. Both were challenged by Gödel's incompleteness theorems, as was Hilbert's formalist programme. Finally, the intuitionists were criticized both philosophically, where their idealism was called into question, and mathematically, where their ability to support a significant body of mathematics remained in doubt. Various modifications have been proposed.

Modifications of logicism. On the mathematical side, a chastened successor to logicism can perhaps be seen in the model-theoretic work of Abraham Robinson and his followers. They are interested in

determining the mathematical content latent in purely 'logical' features of various mathematical structures or the extent to which genuinely mathematical problems concerning these structures can be solved by purely logical (that is, model-theoretic) means. They have been particularly successful in their treatment of various algebraic structures.

Philosophically, too, there have been attempts to renew logicism. It re-emerged in the 1930s and 1940s as the favoured philosophy of mathematics of the logical empiricists. They did not, however, develop a logicism of their own in the way that Dedekind, Frege and Russell did, but, rather, simply appropriated the technical work of Russell and Whitehead (modulo the usual reservations concerning the axioms of infinity and reducibility) and attempted to embed it in an overall empiricist epistemology.

This empiricist turn was a novel development in the history of logicism and represented a serious departure from both the original logicism of LEIBNIZ (§10) and the more recent logicism of Frege (and Dedekind). It was less at odds with Russell's logicism, which saw mathematics and the empirical sciences as both making use of an essentially inductive method (the so-called 'regressive' method).

Like all empiricists, the logical empiricists struggled with the Kantian problem of how to account for the apparent necessity of mathematics while at the same time being able to explain its cognitive richness. Their strategy was to empty mathematics of all non-analytic content while, at the same time, arguing that analytic truth and inference can be substantial and non-self-evident.

Their ideas came under heavy attack by W.V. QUINE, who challenged their pivotal distinction between analytic and synthetic truths. He argued that the basic unit of knowledge – the basic item of our thought that is tested against experience – is science as a whole and that this depends upon empirical evidence for its justification. Mathematics and logic are used to relate empirical evidence to the rest of science and, so, are inextricably interwoven into the whole fabric of science. They are thus part of the total body of science that is tested against experience and there is no clean way of dividing between truths of meaning (analytic truths) and truths of fact (synthetic truths).

Within a relatively brief period of time, Quine's argument became a major influence in the philosophy of mathematics and the logicism of the logical empiricists was largely abandoned. Newer conceptions of logicism have, however, continued to appear from time to time. For example, Putnam addressed the difficult (for a logicist) question of existence claims, arguing that such statements are to be seen as asserting the possible (as opposed to the actual) existence of structures. They are therefore, at bottom, logical claims, and can be established by logical (or metalogical) means. Hodes takes a somewhat different approach, arguing that arithmetic claims can be translated into a second-order logic in which the second-order variables range over functions and concepts (as opposed to objects). In this way, commitment to sets and other specifically mathematical objects can be eliminated and, this done, arithmetic can be considered a part of logic.

Field also presents a kind of logicist view – namely, that mathematical knowledge is (at least largely) logical knowledge. Mathematical knowledge is defined as that knowledge which separates a person who knows a lot of mathematics from a person who knows only a little, and it is then argued that what separates these two kinds of knowers is mainly logical knowledge; that is, knowledge of what follows from what.

Modifications of Hilbert's programme. Hilbert's programme too has its latter-day adherents. For the most part, these have adopted one of two basic stances: that of extending the methods available for proving the consistency of classical ideal mathematics; or that of diminishing the scope and strength of classical ideal mathematics so that its consistency (or the consistency of important parts of it) can more nearly be proved by the kinds of elementary means that Hilbert originally envisaged.

Some in the first group (for example, Gentzen, Ackermann and Gödel) have argued that there are types of evidence that exceed finitary evidence in strength but which have the same basic epistemic virtues as it. Others (for example, Kreisel, Feferman, Sieg) argue for a change in our conception of what a consistency proof ought to do. They maintain that its essential obligation is to realize an epistemic gain, and that finitary methods are not the only epistemically gainful methods for proving consistency.

Those in the second group – the so-called 'reverse mathematics' school of Friedman, Simpson and others – try to isolate the mathematical 'cores' of the various areas of classical mathematics and prove the consistency of these 'reduced' theories by finitary or related means. So far, significant success has been achieved along these lines. (See HILBERT'S PROGRAMME AND FORMALISM.)

Modifications of intuitionism. Regarding intuitionism, Heyting's work in the 1930s to formalize intuitionism and to identify its logic has led to a vigorous programme of logical and mathematical investigation. In addition to Heyting and his students, Errett Bishop and his followers have extended a constructivist approach to areas of

classical mathematics to which such an approach had previously not been extended.

On the more philosophical side, the most important development is the construction by Michael Dummett and his anti-realist followers of a defence of intuitionism based upon – in their view – the best answer to the question ‘What is the logic of mathematics?’. Their answer is based upon what they take to be a proper theory of meaning – a theory which, following certain ideas set out by Wittgenstein in his *Philosophical Investigations*, equates the meaning of an expression with its canonical use in the practice to which it belongs. They then identify the canonical use of an expression in mathematics with the role it plays in the central activity of proof, and from this they infer an intuitionist treatment of the logical operators.

6 Later developments

Along with the modifications of the major post-Kantian viewpoints noted above, two other developments in the second half of the twentieth century are important to note. One of these is the shift towards empiricism that was brought about by Quine’s (following Duhem’s) merging of mathematics and the empirical sciences into a single justificatory unit governed by a basically inductive-empirical method. On this view, mathematics may on the whole be *less* susceptible to falsification by sensory evidence than is natural science, but this is a difference of degree, not kind.

This conception of mathematics dispenses with a ‘datum’ of mathematical epistemology that philosophers of mathematics from Kant on down had struggled to accommodate: namely, the presumed necessity of mathematics. It puts in its place a general empiricist epistemology in which all judgments – those of mathematics and logic as well as those of the natural sciences – are seen as evidentially connected to sensory phenomena and, so, subject to empirical revision.

To accommodate the lingering conviction that mathematics is independent of empirical evidence in a way that natural science is not, Quine introduced a pragmatic distinction between them. Rational belief-revision, he said, is governed by a pragmatic concern to maximize the overall predictive and explanatory power of one’s total system of beliefs. Furthermore, predictive and explanatory power are generally aided by policies of revision which minimize, both in scope and severity, the changes that are made to a previously successful belief-system in response to recalcitrant experience.

Because of this, beliefs of mathematics and logic are typically less subject to empirical revision than beliefs of natural science and common sense since revising them generally (albeit, in Quine’s view, not inevitably) does more damage to a belief-system than does revising its common sense and natural scientific beliefs. The necessity of mathematics is thus accommodated in Quine’s epistemology by moving mathematics closer to the centre of a ‘web’ of human beliefs where beliefs are less susceptible to empirical revision than are the beliefs of natural science and common sense that lie closer to the edge of the web.

In Quine’s view, merging mathematics and science into a single belief-system also induces a realist conception of mathematics. Mathematical sentences must be treated as true in order to play their role in this system, and the world is to be seen as being populated by those entities that are among the values of the variables of true sentences. Mathematical entities are thus real because mathematical sentences play an integral part in our best total theory of experience.

Quine’s views have been challenged on various grounds. For example, Parsons argues that treating the elementary arithmetical parts of mathematics as being on an epistemological par with the hypotheses of theoretical physics fails to capture an epistemologically important distinction between the different kinds of evidentness displayed by the two. Even highly confirmed physical hypotheses such as ‘The earth moves around the sun’ are more ‘derivative’ (that is, roughly, more theory-laden) than is an elementary arithmetic proposition such as ‘7+5=12’. It is therefore not plausible to regard the two claims as based on essentially the same type of evidence.

Others have challenged different aspects of Quine’s position. Field and Maddy, for example, both question his merging of mathematics and natural science, though in different ways. Field argues that natural science that utilizes mathematics is a conservative extension of it and, so, has no need of its entities. The mathematical part of natural science can thus, in an important sense, be separated from the rest of it. Maddy investigates the possibility that our knowledge of at least certain mathematical objects might not be so diffuse and inextricable from the whole scheme of our natural scientific knowledge as Quine suggests. She argues that perceptual experience can be tied closely and specifically to certain mathematical objects (in particular, to certain sets) in a way that seems out of keeping with Quine’s holism.

In addition to Quine, others have suggested different mergings of mathematics and natural sciences. Kitcher, for instance, presents a generally empiricist epistemology for mathematics in which history and community are important

epistemological forces. Gödel, on the other hand, argued that mathematics, like the natural sciences, makes use of what is essentially inductive justification when it justifies higher-level mathematical hypotheses on the grounds of their explanatory or simplificatory effects on lower-level mathematical truths and on physics. He allowed, however, that only *some* of our mathematical knowledge arises from empirical sources and regarded as absurd the idea that all of it might do.

Another important influence on recent philosophy of mathematics is Benacerraf's 'Mathematical Truth' (1973), in which he argues that the philosophy of mathematics faces a general dilemma. It must give an account of both mathematical truth and mathematical knowledge. The former seems to demand abstract objects as the referents of singular terms in mathematical discourse. The latter, on the other hand, seems to demand that we avoid such referents. There are mathematical epistemologies (for example, various Platonist ones) that allow for a plausible account of the truth of mathematical sentences. Likewise, there are those (for example, various formalist ones) that allow for a plausible account of how we might come to *know* mathematical sentences. However, no known epistemology does both. Towards the end of the twentieth century a great deal of work has been devoted to resolving this dilemma. Field, Hellman and Chihara attempt anti-Platonist resolutions. Maddy, on the other hand, attempts a resolution at once Platonist and naturalistic. To date there is no general consensus on which approaches are the more plausible.

An earlier argument of Benacerraf's (see Benacerraf 1965) was similarly influential in shaping later work. It is the chief inspiration of the position known as 'structuralism' – the view that mathematical objects are essentially positions in structures and have no important additional internal composition or nature. Apart from the desire for a descriptively more adequate account of mathematics, the chief motivation of structuralism is epistemological. Knowledge of the characteristics of individual abstract objects would seem to require naturalistically inexplicable powers of cognition. Knowledge of at least some structures, on the other hand, would appear to be explicable as the result of applying such classically empiricist means of cognition as abstraction to observable physical complexes. Structures identified via abstraction become part of the general framework of our thinking and can be extended and generalized in a variety of ways as the search for the simplest and most effective overall conceptual scheme is pursued.

Structuralism as a general philosophy of mathematics has been criticized by Parsons, who argues that there are important mathematical objects for which structuralism is not an adequate account. These are the 'quasi-concrete' objects of mathematics – objects that are directly 'instantiated' or 'represented' by concrete objects (for example, geometric figures and symbols such as the so-called 'stroke numerals' of Hilbert's finitary arithmetic, where these are construed as types whose instances are written marks or symbols or uttered sounds). Such objects cannot be treated in a purely structuralist way because their 'representational' function cannot be reduced to the purely intrastructural relationships they bear to other objects within a given system. At the same time, however, they are among the most elementary and important mathematical entities there are.

MATTER

Viewed as arising within the framework of a more general theory of *substance*, philosophical treatments of matter have traditionally revolved around two issues: (1) The nature of matter: what are the distinguishing characteristics of matter or material substance(s) that define it and distinguish it from other substances, if any? (2) The problem of elements: do material things consist of elementary substances, or are there always further constituents? One possible view is that there is no fundamental level – that there are always further constituents, ingredients of ingredients. However, the view most often held by both philosophers and scientists has

been that there are indeed fundamental *elements* out of which material things are made. Once this view is adopted, the question arises as to what they are and what properties distinguish them.

These two issues were introduced, though only gradually, in ancient Greek philosophy. A significant turn came about in the seventeenth century, in which the work of Descartes and Newton led to a picture of matter as passive, inert and dead as opposed to minds and forces, both of which were conceived as being 'active'. Many philosophical problems and doctrines have been formulated in terms of this distinction. However, later developments in science, especially in the twentieth century, have brought about such profound changes that classical concepts of matter are no longer viable. These new developments profoundly alter the statements of philosophical doctrines and problems traditionally associated with matter.

DUDLEY SHAPERE

MAXWELL, JAMES CLERK (1831–79)

For his two achievements of unifying electricity, magnetism and light, and of inventing statistical dynamics, Maxwell stands as the founding mind of modern theoretical physics. More than any other physicist his also was a mind shaped and informed by a training in philosophy, even though, unlike Heinrich Hertz or Ernst Mach, for example, he never wrote a philosophical treatise. Therein lies the point, however. Mach's and Hertz's best discoveries seem remote from their metaphysics, Maxwell's are bound up with his. Particularly important philosophically are his interconnected uses of relation, analogy and classification. He is also responsible for introducing the word 'relativity' into physics, and for articulating the scientific problematic that led to Einstein's theory.

C.W.F. EVERITT

MEAD, GEORGE HERBERT (1863–1931)

Together with Charles Peirce, William James and John Dewey, George Herbert Mead is considered one of the classic representatives of American pragmatism. He is most famous for his ideas about the specificities of human communication and sociality and about the genesis of the 'self' in infantile development. By developing these ideas, Mead became one of the founders of social psychology and – mostly via his influence on the school of symbolic interactionism – one of the most influential figures in contemporary sociology. Compared to that enormous influence, other parts of his philosophical work are relatively neglected.

MEANING AND RULE-FOLLOWING

Wittgenstein's discussion of rules and rule-following, and the recent responses to it, have been widely regarded as providing the deepest and most challenging issues surrounding the notions of meaning, understanding and intention – central notions in the philosophy of language and mind. The fundamental issue is what it is for words to have meaning, and for speakers to use words in accordance with their meanings. In *Philosophical Investigations* and *Remarks on the Foundations of Mathematics*, Wittgenstein explores the idea that what could give a word its meaning is a rule for its use, and that to be a competent speaker is to use words in accordance with these rules. His discussion of the nature of rules and rule-following has been highly influential, although there is no general agreement about his conclusions and final position. The view that there is no objectivity to an individual's attempt to follow a rule in isolation provides one strand of Wittgenstein's argument against the possibility of a private language.

To some commentators, Wittgenstein's discussion only leads to the sceptical conclusion that there are no rules to be followed and so no facts about what words mean. Others have seen him as showing why certain models of what it takes for an individual to follow a rule are inadequate and must be replaced by an appeal to a communal linguistic practice.

BARRY C. SMITH

MEANING AND TRUTH

Analytic philosophy has seen a resurgent interest in the possibility of explaining linguistic meaning in terms of truth, which many philosophers have seen as considerably more tractable than meaning. The core suggestion is that the meaning of a declarative sentence may be given by specifying certain conditions under which it is true. Thus the declarative sentence 'Venus is red' is true just in case the condition that Venus is red obtains; and this is exactly what the sentence means.

As it stands, however, this suggestion provides us with no explanation of the meanings of the words and phrases that make up sentences, since in general they are not expressions that have truth-conditions. (There are no conditions under which the word 'Venus' is true.) Furthermore, it needs to be supplemented by some method of circumscribing the truth-conditions that embody the meanings of declarative sentences, since there are many conditions under which any given sentence is true: 'Venus is red' is true not merely when Venus is red, but also, for example, when Venus is red and 7 + 5 = 12; but it does not *mean* that Venus is red and 7 + 5 = 12.

Evidently the first problem can be solved only by finding other semantic properties which indicate the meanings of words and phrases. For example, it is sometimes thought that the meaning of a name can be specified by saying what it refers to; and that of a predicate by saying what it is true of. But notice that since the meaning of a declarative sentence can be grasped by first grasping the meanings of its basic components, meaning-indicating ascriptions of semantic properties to those components must entail a meaning-indicating statement of its truth-conditions. Semantic properties such as 'referring to' and 'being true of' satisfy this requirement, at least in the context of what is sometimes called a 'truth theory' for a language.

This still leaves the problem of how to circumscribe the right meaning-indicating statement of truth-conditions for declarative sentences. Indeed we now have a further problem. For if the meanings of the components of sentences are not stated directly, but merely in terms of what they refer to or are true of (say), then we must also find a way of determining which of the many ways of specifying what they refer to, or the conditions under which they are true of something, is meaning-indicating. These problems may arguably be solved by placing an appropriate truth theory for a language in a setting that allows us to appeal to the general psychology of its speakers.

Attempts to elucidate meaning in terms of truth-conditions induce a plethora of further problems. Many are a matter of detail, concerning the kinds of properties we should associate with particular idioms and constructions or, equivalently, how we are to produce truth theories for them. As a result of Tarski's work, we have a good idea how to do this for a wide range of categories of expressions. But there are many which, superficially at least, seem to resist straightforward incorporation into such a framework. More general difficulties concern whether truth should be central at all in the analysis or elucidation of meaning; two objections are especially prominent, one adverting to antirealist considerations, the other to the redundancy theory of truth.

MEANING AND VERIFICATION

The verifiability theory of meaning says that meaning is evidence. It is anticipated in, for example, Hume's empiricist doctrine of impressions and ideas, but it emerges into full notoriety in twentieth-century logical positivism. The positivists used the theory in a critique of metaphysics to show that the problems of philosophy, such as the problem of the external world and the problem of other minds, are not real problems at all but only pseudoproblems. Their publicists used the doctrine to argue that religion, ethics and fiction are meaningless, which is how verificationism became notorious among the general public.

Seminal criticism of verification from around 1950 argues that no division between sense and nonsense coincides tidily with a division between science and metaphysics, as the positivists had claimed. Quine later developed verificationism into a sort of semantic holism in which metaphysics is continuous with science. In contrast, Dummett argues from a reading of Wittgenstein's claim that meaning is use to a rejection of any sort of truth surpassing the possibility of knowledge, and thence to a defence of intuitionistic logic. But the claim that all truths can be known yields in an otherwise innocuous setting the preposterous consequence that all truths actually are known. There are ways to tinker with the setting so as to avoid this consequence, but it is best to conclude by *reductio* that some truths cannot be known and that verificationism is false. That in turn seems to show that the prospects for an empiricist theory of meaning are dim, which might well shake a complacent confidence in meaning.

MEASUREMENT PROBLEM, QUANTUM

See QUANTUM MEASUREMENT PROBLEM

MEASUREMENT, THEORY OF

A conceptual analysis of measurement can properly begin by formulating the two fundamental problems of any measurement procedure. The first problem is that of representation, justifying the assignment of

numbers to objects or phenomena. We cannot literally take a number in our hands and 'apply' it to a physical object. What we can show is that the structure of a set of phenomena under certain empirical operations and relations is the same as the structure of some set of numbers under corresponding arithmetical operations and relations. Solution of the representation problem for a theory of measurement does not completely lay bare the structure of the theory, for there is often a formal difference between the kind of assignment of numbers arising from different procedures of measurement. This is the second fundamental problem, determining the scale type of a given procedure.

Counting is an example of an absolute scale. The number of members of a given collection of objects is determined uniquely. In contrast, the measurement of mass or weight is an example of a ratio scale. An empirical procedure for measuring mass does not determine the unit of mass. The measurement of temperature is an example of an interval scale. The empirical procedure of measuring temperature by use of a thermometer determines neither a unit nor an origin. In this sort of measurement the ratio of any two intervals is independent of the unit and zero point of measurement.

Still another type of scale is one which is arbitrary except for order. Moh's hardness scale, according to which minerals are ranked in regard to hardness as determined by a scratch test, and the Beaufort wind scale, whereby the strength of a wind is classified as calm, light air, light breeze, and so on, are examples of ordinal scales.

A distinction is made between those scales of measurement which are fundamental and those which are derived. A derived scale presupposes and uses the numerical results of at least one other scale. In contrast, a fundamental scale does not depend on others.

Another common distinction is that between extensive and intensive quantities or scales. For extensive quantities like mass or distance an empirical operation of combination can be given which has the structural properties of the numerical operation of addition. Intensive quantities do not have such an operation; typical examples are temperature and cardinal utility.

A widespread complaint about this classical foundation of measurement is that it takes too little account of the analysis of variability in the quantity measured. One important source is systematic variability in the empirical properties of the object being measured. Another source lies not in the object but in the procedures of measurement being used. There are also random errors which can arise from variability in the object, the procedures or the conditions surrounding the observations.

PATRICK SUPPES

MEDICAL ETHICS

Medical ethics was once concerned with the professional obligations of physicians, spelled out in codes of conduct such as the ancient Hippocratic oath and elaborated by contemporary professional societies. Today this subject is a broad, loosely defined collection of issues of morality and justice in health, health care and related fields. The term 'bioethics' is often used interchangeably, though it is also used with its original broad meaning, which included issues in ecology.

The range of concerns grouped under 'medical ethics' begins with the relationship of doctor to patient, including such issues as consent to treatment, truth-telling, paternalism, confidentiality and the duty to treat. Particular moral uncertainty is engendered by contexts which demand divided allegiances of physicians, such as medical experimentation on human subjects, public health emergencies and for-profit medicine. Issues in medical ethics arise in every stage of life, from the fate of defective newborns to the withholding of life-sustaining therapies from the very old. Medical practices with patients who may not be competent to make their own medical decisions, including paediatrics and psychiatry, raise a distinctive set of ethical issues, as does medical genetics, which involves choices affecting family members, future individuals and offspring *in utero*. In recent years, medical ethics has broadened its focus beyond the individual physician or nurse to include the organization, operation and financing of the health care system as a whole, including difficult theoretical and practical uncertainties regarding the fair allocation of health care resources.

Medical ethics is at once a field of scholarship and a reform movement. The latter has campaigned in many countries on behalf of patients' rights, better care of the dying and freedom for women in reproductive decisions. As a field of scholarship, medical ethics addresses these and many other issues, but is not defined by positions taken on any of them. Though ethicists often favour an emphasis on informed consent, oppose paternalism, urge permission to end life-sustaining therapy (or choose suicide) and seek protection of human subjects of experimentation, a diversity of viewpoints finds expression in the medical ethics literature.

DANIEL WIKLER

MEDIEVAL PHILOSOPHY

Medieval philosophy is the philosophy of Western Europe from about AD 400–1400, roughly the period between the fall of Rome and the Renaissance. Medieval philosophers are the historical successors of the philosophers of antiquity, but they are in fact only tenuously connected with them. Until about 1125, medieval thinkers had access to only a few texts of ancient Greek philosophy (most importantly a portion of Aristotle's logic). This limitation accounts for the special attention medieval philosophers give to logic and philosophy of language. They gained some acquaintance with other Greek philosophical forms (particularly those of later Platonism) indirectly through the writings of Latin authors such as Augustine and Boethius. These Christian thinkers left an enduring legacy of Platonistic metaphysical and theological speculation. Beginning about 1125, the influx into Western Europe of the first Latin translations of the remaining works of Aristotle transformed medieval thought dramatically. The philosophical discussions and disputes of the thirteenth and fourteenth centuries record later medieval thinkers' sustained efforts to understand the new Aristotelian material and assimilate it into a unified philosophical system.

The most significant extra-philosophical influence on medieval philosophy throughout its thousand-year history is Christianity. Christian institutions sustain medieval intellectual life, and Christianity's texts and ideas provide rich subject matter for philosophical reflection. Although most of the greatest thinkers of the period were highly trained theologians, their work addresses perennial philosophical issues and takes a genuinely philosophical approach to understanding the world. Even their discussion of specifically theological issues is typically philosophical, permeated with philosophical ideas, rigorous argument and sophisticated logical and conceptual analysis. The enterprise of philosophical theology is one of medieval philosophy's greatest achievements.

The way in which medieval philosophy develops in dialogue with the texts of ancient philosophy and the early Christian tradition (including patristic philosophy) is displayed in its two distinctive pedagogical and literary forms: the textual commentary and the disputation. In explicit commentaries on texts such as the works of Aristotle, Boethius' theological treatises and Peter Lombard's classic theological textbook, the *Sentences*, medieval thinkers wrestled anew with the traditions that had come down to them. By contrast, the disputation – the form of discourse characteristic of the university environment of the later Middle Ages – focuses not on particular texts but on specific philosophical or theological issues. It thereby allows medieval philosophers to gather together relevant passages and arguments scattered throughout the authoritative literature and to adjudicate their competing claims in a systematic way. These dialectical forms of thought and interchange encourage the development of powerful tools of interpretation, analysis and argument ideally suited to philosophical inquiry. It is the highly technical nature of these academic (or scholastic) modes of thought, however, that provoked the hostilities of the Renaissance humanists whose attacks brought the period of medieval philosophy to an end.

1 Historical and geographical boundaries

The terms 'medieval' and 'Middle Ages' derive from the Latin expression *medium aevum* (the middle age), coined by Renaissance humanists to refer to the period separating the golden age of classical Greece and Rome from what they saw as the rebirth of classical ideals in their own day. The humanists were writing from the perspective of the intellectual culture of Western Europe, and insofar as their conception of a middle age corresponds to an identifiable historical period, it corresponds to a period in the history of the Latin West. The historical boundaries of medieval intellectual culture in Western Europe are marked fairly clearly: on the one end by the disintegration of the cultural structures of Roman civilization (Alaric sacked Rome in AD 410), and on the other end by the dramatic cultural revolution perpetrated by the humanists themselves (in the late fourteenth and fifteenth centuries). There is some justification, therefore, for taking 'medieval philosophy' as designating primarily the philosophy of the Latin West from about AD 400–1400.

There were, of course, significant non-Latin philosophical developments in Europe and the Mediterranean world in this same period, in the Greek-speaking Byzantine empire, for example, and in Arabic-speaking Islamic and Jewish cultures in the Near East, northern Africa and Spain. None of these philosophical traditions, however, was radically cut off from the philosophical heritage of the ancient world in the way the Latin-speaking West was by the collapse of the Roman Empire. For that reason, those traditions are best treated separately

from that of western Europe. Accordingly, they are dealt with in this article only to the extent to which they influence developments in medieval philosophy in the Latin West.

(See HUMANISM, RENAISSANCE; ISLAMIC PHILOSOPHY; JEWISH PHILOSOPHY; RENAISSANCE PHILOSOPHY.)

2 Beginnings

The general character of medieval philosophy in the West is determined to a significant extent by historical events associated with the collapse of Roman civilization. The overrunning of Western Europe by invading Goths, Huns and Vandals brought in its wake not only the military and political defeat of the Roman Empire but also the disintegration of the shared institutions and culture that had sustained philosophical activity in late antiquity. Boethius, a Roman patrician by birth and a high-ranking official in the Ostrogothic king's administration, is an eloquent witness to the general decline of intellectual vitality in his own day. He announces his intention to translate into Latin and write Latin commentaries on all the works of Plato and Aristotle, and he gives as his reason the fear that, lacking this sort of remedial aid, his own Latin-speaking and increasingly ill-trained contemporaries will soon lose access altogether to the philosophical legacy of ancient Greece. Boethius' assessment of the situation appears to have been particularly astute, for in fact in the six centuries following his death (until the mid-twelfth century), philosophers in the West depended almost entirely on Boethius himself for what little access they had to the primary texts of Greek philosophy. Moreover, since he had barely begun to carry out his plan when his execution for treason put an end to his work, Boethius' fears were substantially realized. Having translated only Aristotle's treatises on logic together with Porphyry's introduction to Aristotle's *Categories* (see ARISTOTLE; PORPHYRY) and having completed commentaries on only some of the texts he translated, Boethius left subsequent generations of medieval thinkers without direct knowledge of most of Aristotle's thought, including the natural philosophy, metaphysics and ethics, and with no texts of PLATO (though a small portion of the *Timaeus* had been translated and commented on by Calcidius in the fourth century). Medieval philosophy was therefore significantly shaped by what was lost to it. It took root in an environment devoid of the social and educational structures of antiquity, lacking the Greek language and cut off from the rich resources of a large portion of classical thought. Not surprisingly, the gradual reclamation of ancient thought over the course of the Middle Ages had a significant impact on the development of the medieval philosophical tradition.

Medieval philosophy, however, was also shaped by what was left to it and, in particular, by two pieces of the cultural legacy of late antiquity that survived the collapse of Roman civilization. The first of these is the Latin language, which remained the exclusive language of intellectual discourse in Western Europe throughout the Middle Ages and into the Renaissance and Enlightenment. Latin provided medieval thinkers with access to some important ancient resources, including CICERO, Seneca, Macrobius, Calcidius, the Latin Church Fathers (see PATRISTIC PHILOSOPHY), Augustine and Boethius. These Latin sources gave early medieval thinkers a general, if not deep, acquaintance with classical ideas. Augustine is far and away the most significant of these Latin sources. His thought, and in particular his philosophical approach to Christianity and his Christianized Neoplatonist philosophical outlook, profoundly affect every period and virtually every area of medieval philosophy (see §5).

The second significant piece of late antiquity to survive into the Middle Ages is Christianity. Christianity had grown in importance in the late Roman Empire and, with the demise of the empire's social structures, the Church remained until the twelfth century virtually the only institution capable of supporting intellectual culture. It sustained formal education in schools associated with its monasteries, churches and cathedrals, and provided for the preservation of ancient texts, both sacred and secular, in its libraries and scriptoriums. Medieval philosophers received at least some of their formal training in ecclesiastical institutions and most were themselves officially attached to the Church in some way, as monks, friars, priests or clerks. In the later Middle Ages, the study of theology was open only to men who had acquired an arts degree, and the degree of Master of Theology constituted the highest level of academic achievement. Consequently, most of the great philosophical minds of the period would have thought of themselves primarily as theologians. Moreover, in addition to providing the institutional basis for medieval philosophy, Christianity was an important stimulus to philosophical activity. Its ideas and doctrines constituted a rich source of philosophical subject matter. Medieval philosophy, therefore, took root in an intellectual world sustained by the Church and permeated with Christianity's texts and ideas (see §5).

3 Historical development

The full flowering of the philosophical tradition that grows from these beginnings occurs in the period from 1100 to 1400. Two developments are particularly important for understanding the rapid growth and flourishing of intellectual culture in these centuries. The first is the influx into the West of a large and previously unknown body of philosophical material newly translated into Latin from Greek and Arabic sources. The second is the emergence and growth of the great medieval universities.

Recovery of texts. Medieval philosophers before Peter Abelard had access to only a few texts of ancient Greek philosophy: those comprising 'the old logic' (Aristotle's *Categories* and *De interpretatione* and Porphyry's *Isagōgē*) and a small part of Plato's *Timaeus*. Abelard's generation witnessed with great enthusiasm the appearance in the Latin West of the remainder of Aristotle's logical works ('the new logic': the *Prior* and *Posterior Analytics*, the *Topics* and the *Sophistical Refutations*). Over the next hundred years, most of Aristotle's natural philosophy (most importantly the *Physics* and *On the Soul*) and the *Metaphysics* and *Ethics* became available for the first time. Not all of these Aristotelian texts were greeted with the same enthusiasm, nor did medieval philosophers find them all equally congenial or accessible (even in Latin translation). However, it is impossible to overstate the impact that the full Aristotelian corpus eventually had on medieval philosophy. The new texts became the subject of increasingly sophisticated and penetrating scholarly commentary; they were incorporated into the heart of the university curriculum, and over time the ideas and doctrines medieval philosophers found in them were woven into the very fabric of medieval thought. Having never before encountered a philosophical system of such breadth and sophistication, philosophers in the thirteenth and fourteenth centuries understandably thought it appropriate to speak of Aristotle simply as 'the Philosopher'.

As medieval thinkers were rediscovering Aristotle they were also acquiring for the first time in Latin translation the works of important Jewish philosophers such as Avencebrol and MAIMONIDES, and Islamic philosophers such as Avicenna (see IBN SINA) and Averroes (see IBN RUSHD). Some of their works were commentaries on Aristotle (Averroes became known simply as 'the Commentator') whereas some (such as Avicenna's *Metaphysics* and *De anima*) were quasi-independent treatises presenting a Neoplatonized Aristotelianism. Medieval philosophers of this period turned eagerly to these texts for help in understanding the new Aristotle, and they were significantly influenced by them. Averroes's interpretation of Aristotle's *On the Soul*, for example, sparked enormous controversy about the nature of intellect, and Avicenna's metaphysical views helped shape the famous later medieval debates about universals and about the nature of the distinction between essence and existence.

Rise of the universities. As abbot of the monastery at Bec in the 1080s, Anselm of Canterbury addressed his philosophical and theological writings to his monks. By contrast, the great philosophical minds of the next generations, thinkers such as Abelard, Gilbert of Poitiers and Thierry of Chartres, would spend significant parts of their careers in the schools at Paris and Chartres and address a good deal of their work to academic audiences. The growth of these schools and others like them at centres such as Oxford, Bologna and Salerno signals a steady and rapid increase in the vitality of intellectual life in Western Europe. By the middle of the thirteenth century, the universities at Paris and Oxford were the leading centres of European philosophical activity. Virtually all the great philosophers from 1250 to 1350, including Albert the Great, Thomas Aquinas, Bonaventure, John Duns Scotus and William of Ockham, studied and taught in the schools at one or both of these centres. It is partly for this reason that early modern philosophers (who were typically not associated with universities) refer to their medieval predecessors in general as 'the schoolmen'.

The migration of philosophical activity to the universities meant not only the centralization of this activity but also its transformation into an increasingly formal and technical academic enterprise. Philosophical education was gradually expanded and standardized, philosophers themselves became highly trained academic specialists and philosophical literature came to presuppose in its audience both familiarity with the standard texts and issues of the university curriculum and facility with the technical apparatus (particularly the technical logical tools) of the discipline. These features of later medieval philosophy make it genuinely scholastic, that is, a product of the academic environment of the schools.

The philosophical disciplines narrowly construed – logic, natural philosophy, metaphysics and ethics – occupied the centre of the curriculum leading to the basic university degrees, the degrees of Bachelor and Master of Arts. Most of the great philosophers of this period, however, went beyond the arts curriculum to pursue advanced work in theology. The requirements for the degree of Master of Theology included study of the Bible, the Church Fathers and (beginning perhaps in the 1220s) Peter Lombard's *Sentences* (which was complete by 1158).

Designed specifically for pedagogical purposes, the *Sentences* is rich in quotation and paraphrase from authoritative theological sources, surveying respected opinion on issues central to the Christian understanding of the world. From about 1250, all candidates for the degree of Master of Theology were required to lecture and produce a commentary on Lombard's text. This requirement offered a formal occasion for scholars nearing their intellectual maturity to develop and present their own positions on a wide variety of philosophical and theological issues guided (often only quite loosely) by the structure of Lombard's presentation.

By virtue of its historical circumstances, medieval philosophical method had from its beginnings consisted largely in commentary on a well defined and fairly small body of authoritative texts and reflection on a canonical set of issues raised by them. Philosophers in the era of the universities took for granted a much larger and more varied intellectual inheritance, but their approach to philosophical issues remained conditioned by an established textual tradition, and they continued to articulate their philosophical views in explicit dialogue with it. Formal commentary on standard texts flourished both as a pedagogical tool and as a literary form. However, other philosophical forms, including the disputation – the most distinctive philosophical form of the thirteenth and fourteenth centuries – were essentially dialectical. In the university environment, the disputation became a technical tool ideally suited to the pressing task of gathering together, organizing and adjudicating the various claims of a complex tradition of texts and positions.

A disputation identifies a specific philosophical or theological issue for discussion and provides the structure for an informed and reasoned judgment about it. In its basic form, a disputation presents, in order: (1) a succinct statement of the issue to be addressed, typically in the form of a question admitting of a 'yes' or 'no' answer; (2) two sets of preliminary arguments, one supporting an affirmative and the other a negative answer to the question; (3) a resolution or determination of the question, in which the master sets out and defends his own position, typically by drawing relevant distinctions, explaining subtle or potentially confusing points, or elaborating the underlying theoretical basis for his answer; and (4) a set of replies specifically addressing the preliminary arguments in disagreement with the master's stated views. A disputation's two sets of preliminary arguments allow for the gathering together of the most important relevant passages and arguments scattered throughout the authoritative literature. With the arguments on both sides of the question in hand, the master is then ideally positioned to deal with both the conceptual issues raised by the question and the hermeneutical problems presented by the historical tradition. Academic philosophers held disputations in their classrooms and at large university convocations, and they used the form for the literary expression of their ideas. Aquinas' *Summa theologiae*, the individual articles of which are pedagogically simplified disputations, is perhaps the most familiar example of its systematic use as a literary device. The prevalence of the disputational form in later medieval philosophy accounts for its being thought of as embodying 'the scholastic method'.

4 Doctrinal characteristics

At the most basic level, medieval philosophers share a common view of the world that underlies and supports the various specific developments that constitute medieval philosophy's rich detail.

Metaphysics. The common metaphysical ground of medieval philosophy holds that at the most general level reality can be divided into substances and accidents. Substances – Socrates and Browny the donkey are the stock examples – are independent existents and therefore ontologically fundamental. Corporeal substances (and perhaps also certain incorporeal substances) are constituted from matter and form (see Substance). Matter, which in itself is utterly devoid of structure, is the substrate for form (see Matter). Form provides a substance's structure or organization, thereby making a substance the kind of thing it is. Socrates' soul, for example, is the form that gives structure to Socrates' matter, constituting it as the living flesh and blood of a human body and making Socrates a particular human being. Accidents – Socrates' height, for example, or Browny's colour – are also a kind of form, but they take as their substrate not matter as such but a substance: Socrates or Browny. Accidents depend for their existence on substances and account for substances' ontologically derivative characteristics.

Medieval philosophers recognized matter and form, the fundamental constituents of corporeal substances, as fundamental explanatory principles. A thing's matter (or material cause) and its form (or formal cause) provide basic explanations of the thing's nature and behaviour. To these two principles they added two others, the agent (or efficient) cause and the end (or final cause). The agent cause is whatever initiates motion or change; the final cause is the goal or good toward which a particular activity, process, or change is directed.

Medieval philosophers disagreed about extensions and qualifications of this fundamental metaphysical view of the world. They debated, for example, whether incorporeal substances are like corporeal substances in being composed ultimately of matter and form, or whether they are subsistent immaterial forms. They also debated whether substances such as Socrates have just one substantial form (Socrates' rational soul) or many (one form constituting Socrates' body, another making him a living body with certain capacities for motion and cognition (an animal), and another making him a rational animal (a human being)). However, they never doubted the basic correctness of the metaphysical framework of substance and accidents, form and matter, nor are they in any doubt about whether the analytical tools which that framework provides are applicable to philosophical problems generally.

Psychology and epistemology. Medieval philosophers understood the nature of human beings in terms of the metaphysics of form and matter, identifying the human rational soul, the seat of the capacities specific to human beings, with form. All medieval philosophers, therefore, held broadly dualist positions according to which the soul and body are fundamentally distinct. But only some were also substance dualists (or dualists in the Cartesian sense), holding in addition that the soul and body are themselves substances.

Medieval philosophers devote very little attention to what modern philosophers would recognize as the central questions of epistemology (see Epistemology, history of). Until very late in the period, they show little concern for sceptical worries and are not primarily interested in stating the necessary and sufficient conditions for the truth of the claim that some person knows a given proposition. For the most part they assume that we have knowledge of various sorts and focus instead on developing an account of the cognitive mechanisms by which we acquire it. They are especially interested in how we are able to acquire knowledge of universals and necessary truths – objects or truths that are immaterial, eternal and unchanging – given that the world around us is populated with particular material objects subject to change. The answers medieval philosophers give to this question vary considerably, ranging from Platonistic accounts that appeal to our direct intellectual vision (with the aid of divine illumination) of independently existing immutable entities (such as ideas in the divine mind) to naturalistic accounts that appeal to cognitive capacities wholly contained in the human intellect itself that abstract universals from the data provided by sense perception (see Universals).

Ethics. Medieval philosophers share a generically Greek framework of ethical theory, extended and modified to accommodate Christianity. Its main features include an objectivist theory of value, a eudaimonistic account of the human good and a focus on the virtues as central to moral evaluation (see Eudaimonia; Aretē; Virtues and vices). According to the metaphysics of goodness inherited by medieval philosophers from Greek thought, there is a necessary connection between goodness and being. Things are good to the extent to which they have being. Evil or badness is not a positive ontological feature of things but a privation or lack of being in some relevant respect. The ultimate human good or goal of human existence is happiness or beatitude, the perfection of which most medieval philosophers identified as supernatural union with God after this life. The ultimate human good is attained both through the cultivation of the moral virtues and through divine grace in the form of supernaturally infused states and dispositions such as faith, hope and charity, the so-called theological virtues.

Within this framework, medieval philosophers debated whether human beatitude is essentially an affective state (a kind of love for God) or a cognitive state (a kind of knowledge or vision of God), and whether the virtues are strictly necessary for the attainment of beatitude. They also debated whether the rightness or wrongness of some actions depends solely on God's will. Contrary to caricatures of medieval ethics, no one unequivocally endorsed a divine command theory according to which the moral rightness (or wrongness) of *all* acts consists solely in their being approved (or disapproved) by God (see Voluntarism).

Logic and language. Medieval philosophers devote enormous attention – perhaps more attention than philosophers of any period in the history of philosophy apart from the twentieth century – to logic and philosophy of language. This phenomenon is explained primarily by the uniquely important role played by Aristotle's logic in the development of medieval thought. Until the early twelfth century, medieval philosophers' knowledge of Greek philosophy was restricted to a few texts of Aristotelian logic and, by default, those texts largely

set the agenda for philosophical discussion. It is a passage from Porphyry's *Isagōgē*, for example, that enticed first Boethius and, following him, a long line of commentators to take up the philosophical problem of universals (see UNIVERSALS). The texts of the old logic, which remained a central part of the philosophy curriculum in the later Middle Ages, were eventually supplemented by the remaining treatises of Aristotle's logic, among which the *Topics* and the *Sophistical Refutations* in particular sparked intense interest in the forms of philosophical argument and the nature of meaning.

Natural philosophy. Medieval philosophers believed that a complete account of reality must include an account of the fundamental constituents and principles of the natural realm. Their earliest reflections on these matters were inspired primarily by two ancient accounts of the origins and nature of the universe, the biblical story of creation (in Genesis) and Plato's story of the Demiurge's fashioning of the world (in the *Timaeus*) (see PLATO). The confluence of these ancient sources produced a medieval tradition of speculative cosmological thought paradigmatically expressed in discussions of the six days of creation. This topic in particular gave medieval philosophers opportunity to reflect on the nature of the contents of the universe and the principles governing the created realm.

From the late twelfth century, medieval philosophy was profoundly affected by the new Aristotelian natural philosophy and the new scientific treatises by Islamic philosophers. Aristotle's *Physics* in particular received enormous attention, and medieval philosophers developed sophisticated tools of logical, conceptual and mathematical analysis to deal with problems raised by Aristotle's discussions of motion, change, continuity and infinity. Scientific treatises by Islamic thinkers such as Alkindi, Alpetragius, Avicenna (see IBN SINA) and Alhasen provided the material and impetus for significant developments in astronomy, medicine, mathematics and optics.

(See OXFORD CALCULATORS.)

5 Philosophical theology

Christianity is not in itself a philosophical doctrine, but it profoundly influences the medieval philosophical world-view both from within philosophy and from outside it. On the one hand, Christian texts and doctrine provided rich subject matter for philosophical reflection, and the nature and central claims of Christianity forced medieval intellectuals to work out a comprehensive account of reality and to deal explicitly with deep issues about the aims and methods of the philosophical enterprise. In these ways, Christianity was taken up into philosophy, adding to its content and altering its structure and methods. On the other hand, Christianity imposed external constraints on medieval philosophy. At various times these constraints took institutional form in the official proscription of texts, the condemnation of philosophical positions and the censure of individuals.

Augustine laid the foundation for medieval Christian philosophical theology in two respects. First, he provided a theoretical rationale both for Christian intellectuals engaging in philosophical activity generally and for their taking Christian doctrine in particular as a subject of philosophical investigation. According to Augustine, Christian belief is not opposed to philosophy's pursuit of truth but is an invaluable supplement and aid to philosophy. With revealed truth in hand, Christian philosophers are able to salvage what is true and useful in pagan philosophy while repudiating what is false. Moreover, Augustine argued that Christianity can be strengthened and enriched by philosophy. Christian philosophers should begin by believing (on the authority of the Bible and the Church) what Christianity professes and seek (by the use of reason) to acquire understanding of what they initially believed on authority. In seeking understanding, philosophers rely on that aspect of themselves – namely, reason – in virtue of which they most resemble God; and in gaining understanding, they strengthen the basis for Christian belief. The Augustinian method of belief seeking understanding is taken for granted by the vast majority of philosophers in the Middle Ages.

Second, Augustine's writings provide a wealth of rich and compelling examples of philosophical reflection on topics ranging from the nature of evil and sin to the nature of the Trinity. Boethius stands with Augustine in this respect as an important model for later thinkers. He composed several short theological treatises that consciously attempt to bring the tools of Aristotelian logic to bear on issues associated with doctrines of the Christian creed. Inspired by the philosophical analysis and argumentation prominent in these writings, medieval philosophers enthusiastically took up, developed and extended the enterprise of philosophical theology.

With the emergence of academic structure in the new European schools and universities of the twelfth and thirteenth centuries, theology became the paramount academic discipline in a formal curriculum of higher education. However, the fact that great thinkers of the later Middle Ages typically studied philosophy as preparatory for the higher calling of theology should not be taken to imply that in becoming theologians they left philosophy

behind. As a simple matter of fact, later medieval theologians continued throughout their careers to address fundamental philosophical issues in fundamentally philosophical ways. And it is clear why this should be so: those who took up the study of theology were among the most gifted and highly trained philosophical minds of their day, and they brought to theology acute philosophical sensitivities, interests and skills. Moreover, in so far as they viewed Christianity as offering the basic framework for a comprehensive account of the world, they were naturally attracted to the broadly philosophical task of building on that framework, understanding its ramifications and resolving its difficulties.

Despite the dominance of the Augustinian view of the relation between Christianity and philosophy, religiously motivated resistance to philosophy in general and to the use of philosophical methods for understanding Christianity in particular emerges in different forms throughout the Middle Ages. In the twelfth century, some influential clerics saw the flourishing study of logic at Paris as a dangerous influence on theology and used ecclesiastical means to attack Peter Abelard and Gilbert of Poitiers. In the thirteenth century the new Aristotelian natural philosophy prompted another period of sustained ecclesiastical reaction. In 1210 and 1215 ecclesiastical authorities proscribed the teaching of Aristotle's natural philosophy at Paris, and in 1277 the Bishop of Paris issued a condemnation of 219 articles covering a wide range of theological and philosophical topics. The condemnation seems largely to have been a reaction to the work of radical Averroistic interpreters of Aristotle. It is unclear how effective these actions were in suppressing the movements and doctrines they targeted.

(See Natural theology.)

6 Scholarship in medieval philosophy

Contemporary study of medieval philosophy faces special obstacles. First, a large body of medieval philosophical and theological literature has survived in European libraries, but because many of these collections have not yet been fully catalogued, scholars do not yet have a complete picture of what primary source materials exist. Second, the primary sources themselves – in the form of handwritten texts and early printed editions – can typically be deciphered and read only by those with specialized paleographical skills. Only a very small portion of the known extant material has ever been published in modern editions of a sort that any reader of Latin could easily use. Third, an even smaller portion of the extant material has been translated into English (or any other modern language) or subjected to the sort of scholarly commentary and analysis that might open it up to a wider philosophical audience. For these reasons, scholarship in medieval philosophy is still in its early stages and remains a considerable distance from attaining the sort of authoritative and comprehensive view of its field now possessed by philosophical scholars of other historical periods with respect to their fields. For the foreseeable future, its progress will depend not only on the sort of philosophical and historical analysis constitutive of all scholarship in the history of philosophy but also on the sort of textual archeology necessary for recovering medieval philosophy's primary texts.

SCOTT MACDONALD

NORMAN KRETZMANN

MEINONG, ALEXIUS (1853–1920)

Meinong was an Austrian philosopher and psychologist who taught at the University of Graz. He contributed substantially to psychology, epistemology, value theory, ethics and probability theory, but is best known for his theory of objects, in which he advocates the radical view that there are objects which are wholly outside being, including impossible objects. Meinong influenced Russell and the American 'new realists'. Though widely rejected, his views have proved difficult to refute decisively

and he has found sympathetic support from a number of logicians and philosophers.

PETER SIMONS

MEISTER ECKHART (*c.*1260–1327/8)

More than any other medieval thinker, Eckhart has received widely divergent interpretations. The controversies stem from the fact that his writings fall into two distinct groups, works written in the vernacular and works written in Latin. The German writings, which were intended for a wide audience, established Eckhart's long-standing fame as a mystic. Another, more academic Eckhart emerged when his Latin work was rediscovered in 1886. The study of Eckhart's thought today centres on the unity of the scholastic (Latin) and the popular (German) work.

JAN A. AERTSEN

MELANCHTHON, PHILIPP (1497–1560)

Philipp Melanchthon was one of Luther's closest associates, helping to systematize Lutheran theology, and his *Loci communes* (Commonplaces) (1521) was one of the most influential early works of Protestant theology. He was often a moderating influence in theological debates between Catholics and Protestants. Melanchthon was also involved in controversy over the relationship between human will and God's grace in the achievement of salvation. He was responsible for the reform of Protestant German education in the sixteenth century, through the large number of textbooks which he composed, and through his revisions of the statutes of universities (notably Wittenberg) and schools. As a scholar and reformer of education, he was a staunch follower of the humanism of Agricola and Erasmus, committed to teaching the best Latin authors and the Greek language. Many of his works are textbooks (often produced in different versions), frequently based on lecture notes, summarizing or commenting on classical authors or scripture. Although more important as a summarizer and popularizer than as a source of new ideas, Melanchthon nevertheless made important contributions to the development of logic, rhetoric, ethics and psychology, as well as to aspects of Reformation theology. In logic he contributed to the growth of interest in method. In ethics he established a place for classical moral teaching alongside but subordinate to the teaching of the Bible. His favourite philosopher was Aristotle, and he tended to pour scorn on rival ancient schools of philosophy. In psychology he favoured a simplified Aristotelianism, close to medieval faculty psychology, with strong emphasis on links with biology. He opposed scepticism wherever he encountered it.

PETER MACK

MEMORY, EPISTEMOLOGY OF

Memory appears to preserve knowledge, but there are epistemic questions about how this could be. Memory is fallible, and empirical research has identified various ways in which people systematically misremember. Even wholesale error seems possible: Russell proposed that it is logically possible for the world to have sprung into existence five minutes ago, complete with spurious ostensible memories of earlier times. In light of such possibilities, some sceptics argue that memory cannot yield knowledge.

Assuming that memory provides knowledge, there are serious epistemic issues about how it does this. For instance, does some introspectible quality of remembering provide distinctive evidence for what is remembered, or is it some other feature of memory that secures the epistemic justification needed for knowledge? How readily recollectible must a proposition be in order for it to be known while it is not being recalled? Does a full retention in memory of a previous basis for knowing something assure continuing knowledge of it? Does forgetting an original basis for knowing without replacing it imply a loss of knowledge?

EARL CONEE

MENCIUS (4th century BC)

Mencius (Mengzi) was a Chinese Confucian philosopher, best known for his claim that human nature is good. He is probably the single most influential philosopher in the Chinese tradition, in that an interpretation of his thought became the basis of the civil service examinations in China in the fourteenth century and remained so for almost 600 years. The primary source for his thought is the collection of his sayings, debates and discussions known as the *Mengzi*.

BRYAN W. VAN NORDEN

MENDELSSOHN, MOSES (1729–86)

A Jewish disciple of Leibniz and Wolff, Mendelssohn strove throughout his life to uphold and strengthen their rationalist metaphysics while

sustaining his ancestral religion. His most important philosophic task, as he saw it, was to refine and render more persuasive the philosophical proofs for the existence of God, providence and immortality. His major divergence from Leibniz was in stressing that 'the best of all possible worlds', which God had created, was in fact more hospitable to human beings than Leibniz had supposed. Towards the end of his life, the irrationalism of Jacobi and the critical philosophy of Kant shook Mendelssohn's faith in the demonstrability of the fundamental metaphysical precepts, but not his confidence in their truth. They would have to be sustained by 'common sense', he reasoned, until future philosophers succeeded in restoring metaphysics to its former glory. While accepting Wolff's teleological understanding of human nature and natural law, Mendelssohn placed far greater value on human freedom and outlined a political philosophy that protected liberty of conscience. His philosophic defence of his own religion stressed that Judaism is not a 'revealed religion' demanding acceptance of particular dogmas but a 'revealed legislation' requiring the performance of particular actions. The object of this divine and still valid legislation, he suggested, was often to counteract forces that might otherwise subvert the natural religion entrusted to us by reason. To resolve the tension between his own political liberalism and the Bible's endorsement of religious coercion, Mendelssohn argued that contemporary Judaism, at any rate, no longer acknowledges any person's authority to compel others to perform religious acts.

MENTAL CAUSATION

Both folk and scientific psychology assume that mental events and properties participate in causal relations. However, considerations involving the causal completeness of physics and the apparent non-reducibility of mental phenomena to physical phenomena have challenged these assumptions. In the case of mental *events* (such as someone's thinking about Vienna), one proposal has been simply to identify not '*types*' (or classes) of mental events with *types* of physical events, but merely individual '*token*' mental events with *token* physical ones, one by one (your and my thinking about Vienna may be 'realized' by different type physical states).

The role of mental *properties* (such as 'being about Vienna') in causation is more problematic. Properties are widely thought to have three features that seem to render them causally irrelevant: (1) they are 'multiply-realizable' (they can be realized in an indefinite variety of substances); (2) many of them seem not to supervene on neurophysiological properties (differences in mental properties do not always depend merely on differences in neurophysiological ones, but upon relations people bear to things outside their skin); and (3) many of them (for example, 'being painful') seem inherently 'subjective' in a way that no objective physical properties seem to be. All of these issues are complicated by the fact that there is no consensus concerning the nature of causal relevance for properties in general.

BARRY LOEWER

MENTAL ILLNESS, CONCEPT OF

The mad were once thought to be wicked or possessed, whereas now they are generally thought to be sick, or mentally ill. Usually, this is regarded as a benign decision by a more enlightened age, but some see it as a double-edged sword – one that simultaneously relieved and robbed the mad of responsibility for their actions, eventually delivering more compassionate treatment, but also disguising value-laden judgments as objective science. The issue is made more difficult by the diversity of conditions classified as psychiatric disorders, and by the extent to which their causes are still ill understood. But the difficulty is also conceptual: what, after all, is physical illness? People usually agree that it involves abnormal body functioning, but how do we decide what is normal functioning? And even supposing that we know what we mean by a sick body, is there a parallel notion of a sick mind that is more than metaphor?

MENTION

See Use/mention distinction and quotation

MEREOLOGY

Mereology is the theory of the part–whole relation and of derived operations such as the mereological sum. (The sum of several things is the smallest thing of which they are all parts.) It was introduced by Leśniewski to avoid Russell's paradox.

Unlike the set-membership relation, the part–whole relation is transitive. This makes mereology much weaker than set theory, but gives the advantage of ontological parsimony. For example, mereology does not posit the proliferation of entities found in set theory, such as $\emptyset, \{\emptyset\}, \{\{\emptyset\}\}, \ldots$.

Mereology has occasioned controversy: over whether many things really have a mereological sum if they are either scattered or, even worse, of different categories; over the uniqueness of sums; and over Lewis' claim that the non-empty subsets of a set are literally parts of it.

PETER FORREST

MERLEAU-PONTY, MAURICE (1908–61)

Merleau-Ponty belongs to the group of French philosophers who transformed French philosophy in the early post-war period by introducing the phenomenological methods of the German philosophers Husserl and Heidegger. His central concern was with 'the phenomenology of perception' (the title of his major book), and his originality lay in his account of the role of the bodily sense-organs in perception, which led him to develop a phenomenological treatment of the sub-personal perceptions that play a central role in bodily movements. This account of the sub-personal aspects of life enabled him to launch a famous critique of Sartre's conception of freedom, which he regarded as an illusion engendered by excessive attention to consciousness. None the less, he and Sartre cooperated for many years in French political affairs, until Merleau-Ponty became exasperated by the orthodox Marxism-Leninism of the French Communist Party in a way in which Sartre, who remained a fellow-traveller, did not. As well as several substantial political essays, Merleau-Ponty wrote widely on art, anthropology and, especially, language. He died leaving some important work incomplete.

Although his work is still esteemed within the French academic establishment, his influence in France has waned, because of a tendency there to study his German forebears almost to the exclusion of all else. But elsewhere, and most notably in the USA, Merleau-Ponty's work is widely studied, especially now that questions about the distinction between personal and sub-personal aspects of life have become so prominent.

THOMAS BALDWIN

METAPHOR

A standard dictionary definition describes a metaphor as 'a figure of speech in which a word or phrase literally denoting one kind of object is used in place of another to suggest a likeness between them'. Although the theoretical adequacy of this definition may be questioned, it conveys the standard view that there is a difference between literal and nonliteral language; that figurative speech is nonliteral language; and that a metaphor is an instance of figurative speech.

The three most influential treatments of metaphor are the comparison, interaction and speech act theories. According to the first, every metaphor involves a comparison; a specific version of this view is that every metaphor is an abbreviated simile. According to the second, every metaphor involves a semantic interaction between some object or concept that is literally denoted by some word, and some concept metaphorically predicated on that word. According to the third, it is not words or sentences that are metaphorical but their use in specific situations; thus, to understand how metaphors function, one must understand how people communicate with language.

A.P. MARTINICH

METAPHYSICS

Introduction

Metaphysics is a broad area of philosophy marked out by two types of inquiry. The first aims to be the most general investigation possible into the nature of reality: are there principles applying to everything that is real, to all that is? – if we abstract from the particular nature of existing things that which distinguishes them from each other, what can we know about them merely in virtue of the fact that they exist? The second type of inquiry seeks to uncover what is ultimately real, frequently offering answers in sharp contrast to our everyday experience of the world. Understood in terms of these two questions, metaphysics is very closely related to ontology, which is usually taken to involve both 'what is existence (being)?' and 'what (fundamentally distinct) types of thing exist?' (see Ontology).

The two questions are not the same, since someone quite unworried by the possibility that the world might really be otherwise than it appears (and therefore regarding the second investigation as a completely trivial one) might still be engaged by

the question of whether there were any general truths applicable to all existing things. But although different, the questions are related: one might well expect a philosopher's answer to the first to provide at least the underpinnings of their answer to the second. Aristotle proposed the first of these investigations. He called it 'first philosophy', sometimes also 'the science of being' (more-or-less what 'ontology' means); but at some point in antiquity his writings on the topic came to be known as the 'metaphysics' – from the Greek for 'after natural things', that is, what comes after the study of nature. This is as much as we know of the origin of the word (see Aristotle §11 and following). It would, however, be quite wrong to think of metaphysics as a uniquely 'Western' phenomenon. Classical Indian philosophy, and especially Buddhism, is also a very rich source (see Buddhist philosophy, Indian; Hindu philosophy; Jaina philosophy).

1 General metaphysics

Any attempt on either question will find itself using, and investigating, the concepts of being and existence (see Being; Existence). It will then be natural to ask whether there are any further, more detailed classifications under which everything real falls, and a positive answer to this question brings us to a doctrine of categories (see Categories). The historical picture here is complex, however. The two main exponents of such a doctrine are Aristotle and Kant. In Aristotle's case it is unclear whether he saw it as a doctrine about things and their basic properties or about language and its basic predicates; whereas Kant quite explicitly used his categories as features of our way of thinking, and so applied them only to things as they appear to us, not as they really or ultimately are (see Kant, I.). Following on from Kant, Hegel consciously gave his categories both roles, and arranged his answer to the other metaphysical question (about the true underlying nature of reality) so as to make this possible (see Hegel, G.W.F.).

An early, extremely influential view about reality seen in the most general light is that it consists of things and their properties – individual things, often called particulars, and properties, often called universals, that can belong to many such individuals (see Particulars; Universals). Very closely allied to this notion of an individual is the concept of substance, that in which properties 'inhere' (see Substance). This line of thought (which incidentally had a biological version in the concepts of individual creatures and their species) gave rise to one of the most famous metaphysical controversies: whether universals are real entities or not (see Species; Natural kinds). In different ways, Plato and Aristotle had each held the affirmative view; nominalism is the general term for the various versions of the negative position (see Nominalism).

The clash between realists and nominalists over universals can serve to illustrate a widespread feature of metaphysical debate. Whatever entities, forces and so on may be proposed, there will be a *prima facie* option between regarding them as real beings, genuine constituents of the world and, as it were, downgrading them to fictions or projections of our own ways of speaking and thinking (see Objectivity). This was, broadly speaking, how nominalists wished to treat universals; comparable debates exist concerning causality (see Causation), moral value (see Emotivism; Moral realism; Moral scepticism) and necessity and possibility (see Necessary truth and convention) – to name a few examples. Some have even proposed that the categories (see above) espoused in the Western tradition are reflections of the grammar of Indo-European languages, and have no further ontological status (see Sapir-Whorf hypothesis).

Wittgenstein famously wrote that the world is the totality of facts, not of things, so bringing to prominence another concept of the greatest generality (see Facts). Presumably he had it in mind that exactly the same things, differently related to each other, could form very different worlds; so that it is not things but the states of affairs or facts they enter into which determine how things are. The apparent obviousness of the formula 'if it is true that *p* then it is a fact that *p*', makes it seem that facts are in one way or another closely related to truth (see Truth, coherence theory of; Truth, correspondence theory of) – although it should be said that not every philosophical view of the nature of truth is a metaphysical one, since some see it as just a linguistic device (see Truth, deflationary theories of) and some as a reflection, not of how the world is, but of human needs and purposes (see Truth, pragmatic theory of; Relativism).

Space and time, as well as being somewhat elusive in their own nature, are further obvious candidates for being features of everything that exists (see Space; Time). But that is controversial, as the debate about the existence of abstract objects testifies (see Abstract objects). We commonly speak, at least, as if we thought that numbers exist, but not as if we thought that they have any spatio-temporal properties. Kant regarded his things-in-themselves as neither spatial nor temporal; and some have urged us to think of God in the same way (see God, concepts of). There are accounts of the

mind which allow mental states to have temporal, but deny them spatial properties (see DUALISM).

Be all this as it may, even if not literally everything, then virtually everything of which we have experience is in time. Temporality is therefore one of the phenomena that should be the subject of any investigation which aspires to maximum generality. Hence, so is change (see CHANGE). And when we consider change, and ask the other typically metaphysical question about it ('what is really going on when something changes?') we find ourselves faced with two types of answer. One type would have it that a change is an alteration in the properties of some enduring thing (see CONTINUANTS). The other would deny any such entity, holding instead that what we really have is merely a sequence of states, a sequence which shows enough internal coherence to make upon us the impression of one continuing thing (see MOMENTARINESS, BUDDHIST DOCTRINE OF). The former will tend to promote 'thing' and 'substance' to the ranks of the most basic metaphysical categories; the latter will incline towards events and processes (see EVENTS; PROCESSES). It is here that questions about identity over time become acute, particularly in the special case of those continuants (or, perhaps, processes), which are persons (see IDENTITY; PERSONS; PERSONAL IDENTITY).

Two major historical tendencies in metaphysics have been idealism and materialism, the former presenting reality as ultimately mental or spiritual, the latter regarding it as wholly material (see IDEALISM; MATERIALISM; MATERIALISM IN THE PHILOSOPHY OF MIND). In proposing a single ultimate principle both are monistic (see MONISM). They have not had the field entirely to themselves. A minor competitor has been neutral monism, which takes mind and matter to be different manifestations of something in itself neither one nor the other (see NEUTRAL MONISM). More importantly, many metaphysical systems have been dualist, taking both to be fundamental, and neither to be a form of the other (see SĀṄKHYA). Both traditions are ancient. In modern times idealism received its most intensive treatment in the nineteenth century (see ABSOLUTE, THE; GERMAN IDEALISM); in the second half of the twentieth century, materialism has been in the ascendant. A doctrine is also found according to which all matter, without actually being mental in nature, has certain mental properties (see PANPSYCHISM).

2 Specific metaphysics

There is also metaphysics that arises in reference to particular subject matters, this being therefore metaphysical primarily with regard to the second question (what are things ultimately like? – or, what kinds of thing ultimately exist?) rather than the first. One of the most obvious cases, and historically the most prominent, is theology; we have already mentioned the philosophy of mind, the philosophy of mathematics and the theory of values. Less obviously, metaphysical issues also intrude on the philosophy of language and logic, as happens when it is suggested that any satisfactory theory of meaning will have to posit the existence of intensional entities, or that any meaningful language will have to mirror the structure of the world (see INTENSIONAL ENTITIES; LOGICAL ATOMISM). The political theorist or social scientist who holds that successful explanation in the social sphere must proceed from properties of societies not reducible to properties of the individuals who make them up (thereby making a society an entity that is in a sense more basic than its members) raises a metaphysical issue (see HOLISM AND INDIVIDUALISM IN HISTORY AND SOCIAL SCIENCE). Metaphysics, as demarcated by the second question, can pop up anywhere.

The relationship with metaphysics is, however, particularly close in the case of science and the philosophy of science. Aristotle seems to have understood his 'first philosophy' as continuous with what is now called his physics, and indeed it can be said that the more fundamental branches of natural science are a kind of metaphysics as it is characterized here. For they are typically concerned with the discovery of laws and entities that are completely general, in the sense that everything is composed of entities and obeys laws. The differences are primarily epistemological ones, the balance of a priori considerations and empirical detail used by scientists and philosophers in supporting their respective ontological claims. The *subject matter* of these claims can even sometimes coincide: during the 1980s the reality of possible worlds other than the actual one was maintained by a number of writers for a variety of reasons, some of them recognizably 'scientific', some recognizably 'philosophical' (see POSSIBLE WORLDS). And whereas we find everywhere in metaphysics a debate over whether claims should be given a realist or an antirealist interpretation, in the philosophy of science we find a parallel controversy over the status of the entities featuring in scientific theories (see REALISM AND ANTIREALISM; SCIENTIFIC REALISM AND ANTIREALISM).

It is true that there has been considerable reluctance to acknowledge any such continuity. A principal source of this reluctance has been logical positivism, with its division of propositions into those which are empirically verifiable and meaningful, and those which are not so verifiable and are either analytic or meaningless, followed up by its

equation of science with the former and metaphysics with the latter (see Logical positivism; Meaning and verification). When combined with the belief that analytic truths record nothing about the world, but only about linguistic convention, this yields a total rejection of all metaphysics – let alone of any continuity with science. But apart from the fact that this line of thought requires acceptance of the principle about meaninglessness, it also makes a dubious epistemological assumption: that what we call science never uses non-empirical arguments, and that what we regard as metaphysics never draws on empirical premises. Enemies of obscurantism need not commit themselves to any of this; they can recognize the continuity between science and metaphysics without robbing anyone of the vocabulary in which to be rude about the more extravagant, ill-evidenced, even barely meaningful forms which, in the view of some, metaphysics has sometimes taken.

Even the philosopher with a low opinion of the prospects for traditional metaphysics can believe that there is a general framework which we in fact use for thinking about reality, and can undertake to describe and explore it. This project, which can claim an illustrious ancestor in Kant, has in the twentieth century sometimes been called descriptive metaphysics, though what it inquires into are our most general patterns of thought, and the nature of things themselves only indirectly, if at all. Though quite compatible with a low estimate of traditional metaphysics as defined by our two primary questions, it does imply that there is a small but fairly stable core of human thought for it to investigate. Hence it collides with the view of those who deny that there is any such thing (see Postmodernism).

METHODOLOGICAL INDIVIDUALISM

Methodological individualism is the thesis that certain psychological properties are *intrinsic* properties, such as 'being made out of iron', rather than externally *relational* properties, such as 'being an aunt'. It has been challenged by influential 'anti-individualist' claims of, for example, Putnam and Burge, according to which the content of an individual's words or thoughts (beliefs, desires) is determined in part by facts about their social or physical environment. Putnam, for example, imagines a planet, 'twin earth', which is identical to the earth in 1750 (prior to modern chemistry) in all respects except that wherever earth had H_2O, twin earth had a different but superficially similar chemical, XYZ. Putnam argues that the English word 'water' in 1750 referred only to H_2O, while the twin word 'water' refers only to XYZ.

Historically, the term 'methodological individualism' has referred to the thesis that all social explanation must be ultimately expressible in terms of facts about individual human beings; not about economic classes, nations and so on. For a treatment of this subject, see Explanation in history and social science.

MILL, JOHN STUART (1806–73)

Introduction

John Stuart Mill, Britain's major philosopher of the nineteenth century, gave formulations of his country's empiricist and liberal traditions of comparable importance to those of John Locke. His distinctive contribution was to bring those traditions into contact with the ideas of nineteenth-century Europe. He impressively united the radicalism of Enlightenment reason with the historical insights of the nineteenth century and he infused English liberalism with high Romantic notions of culture and character.

Mill held that all knowledge is based on experience, believed that our desires, purposes and beliefs are products of psychological laws of association, and accepted Bentham's standard of the greatest total happiness of all beings capable of happiness – the principle of 'utility'. This was his Enlightenment legacy.

In epistemology Mill's empiricism was very radical. He drew a distinction between 'verbal' and 'real' propositions similar to that which Kant made between analytic and synthetic judgments. However, unlike Kant, Mill held that not only pure mathematics but logic itself contains real propositions and

inferences, and unlike Kant, he denied that any synthetic, or real, proposition is a priori. The sciences of logic and mathematics, according to Mill, propound the most general laws of nature and, like all other sciences, are in the last resort grounded inductively on experience.

We take principles of logic and mathematics to be a priori because we find it inconceivable that they should not be true. Mill acknowledged the facts which underlie our conviction, facts about unthinkability or imaginative unrepresentability, and he sought to explain these facts in associationist terms. He thought that we are justified in basing logical and mathematical claims on such facts about what is thinkable – but the justification is itself a posteriori.

What then is the nature and standing of induction? Mill held that the primitive form of induction is enumerative induction, simple generalization from experience. He did not address Hume's sceptical problem about enumerative induction. Generalization from experience is our primitive inferential practice and remains our practice when we become reflectively conscious of it – in Mill's view nothing more needs to be said or can be said. Instead he traced how enumerative induction is internally strengthened by its actual success in establishing regularities, and how it eventually gives rise to more searching methods of inductive inquiry, capable of detecting regularities where enumerative induction alone would not suffice. Thus whereas Hume raised sceptical questions about induction, Mill pushed through an empiricist analysis of deduction. He recognized as primitively legitimate only the disposition to rely on memory and the disposition to generalize from experience. The whole of science, he thought, is built from these.

In particular, he did not accept that the mere fact that a hypothesis accounts for data can ever provide a reason for thinking it true (as opposed to thinking it useful). It is always possible that a body of data may be explained equally well by more than one hypothesis. This view, that enumerative induction is the only authoritative source of general truths, was also important in his metaphysics. Accepting as he did that our knowledge of supposed objects external to consciousness consists only in the conscious states they excite in us, he concluded that external objects amount only to 'permanent possibilities of sensation'. The possibilities are 'permanent' in the sense that they can be relied on to obtain if an antecedent condition is realized. Mill was the founder of modern phenomenalism.

In ethics, Mill's governing conviction was that happiness is the sole ultimate human end. As in the case of induction, he appealed to reflective agreement, in this case of desires rather than reasoning dispositions. If happiness was not 'in theory and in practice, acknowledged to be an end, nothing could ever convince any person that it was so' (*Utilitarianism* 1861). But he acknowledged that we can will to do what we do not desire to do; we can act from duty, not desire. And he distinguished between desiring a thing as 'part' of our happiness and desiring it as a means to our happiness. The virtues can become a part of our happiness, and for Mill they ideally should be so. They have a natural base in our psychology on which moral education can be built. More generally, people can reach a deeper understanding of happiness through education and experience: some forms of happiness are inherently preferred as finer by those able to experience them fully.

Thus Mill enlarged but retained Bentham's view that the happiness of all, considered impartially, is the standard of conduct. His account of how this standard relates to the fabric of everyday norms was charged with the nineteenth century's historical sense, but also maintained links with Bentham. Justice is a class of exceptionally stringent obligations on society – it is the 'claim we have on our fellow-creatures to join in making safe for us the very groundwork of our existence' (*Auguste Comte and Positivism* 1865). Because rights of justice protect this groundwork they take priority over the direct pursuit of general utility as well as over the private pursuit of personal ends.

Mill's doctrine of liberty dovetails with this account of justice. Here he appealed to rights founded on 'utility in the largest sense, grounded on the permanent interests of man as a progressive being' (*On Liberty* 1859). The principle enunciated in this essay safeguards people's freedom to pursue their own goals, so long as they do not infringe on the legitimate interests of others: save in 'backward states of society, power should not be exercised over people for their own good. Mill defended the principle on two grounds. It enables individuals to realize their potential in their own distinctive way, and, by liberating talents, creativity and energy, it institutes the social conditions for the moral development of culture and character.

1 Life

Mill was born in London on 20 May 1806, the eldest son of a Scotsman, James MILL, and an English woman, Harriet Burrow. James educated his son himself – an education made famous by the account John Stuart gave of it in his *Autobiography* (1873). He taught John the classics, logic, political economy, jurisprudence and psychology – starting with Greek at the age of three. John was brought up in a circle of intellectual and political radicals, friends of his father, which included Jeremy BENTHAM and David Ricardo. In his twenties (not surprisingly, perhaps) he was afflicted by a deep depression from which he recovered partly through reading poetry. In those and subsequent years he also came to know some of the most interesting younger figures in English politics and culture. These included conservative critics of Benthamism, as well as radical adherents to it.

Mill followed his father into the East India Company, where he became an influential official, resigning only in 1858 when, following the Indian Mutiny, the Company was taken over by the Crown and the governance of India became the direct business of the British State. In 1851 he married Harriet Taylor, who, according to his own account, greatly influenced his social philosophy. In the 1860s he was briefly a member of Parliament, and throughout his life was involved in many radical causes. Among them was his lifelong support for women's rights – see *The Subjection of Women* (1869).

Mill made his philosophical reputation with his *System of Logic*, published in 1843. The *Principles of Political Economy* (1848) was a synthesis of classical economics which defined liberal orthodoxy for at least a quarter of a century. His two best-known works of moral philosophy, *On Liberty* and *Utilitarianism*, appeared later – in 1859 and 1861. But he had been thinking about ethics and politics all his life, and it is his moral and political philosophy which is at present most widely read.

2 Language and logic

Nevertheless, Mill's epistemology and metaphysics remain as interesting and relevant as his better-known views in ethics and politics, and it is from these aspects of his philosophy that a general survey must start. In the *System of Logic* Mill distinguishes 'verbal' and 'real' propositions, and correspondingly, 'merely apparent' and 'real' inferences. An inference is merely apparent when no move to a new assertion has been made. For this to be so, the conclusion must literally have been asserted in the premises. In such a case, there can be no epistemological problem about justifying the apparent inference – there *is* nothing to justify. A verbal proposition can now be defined as a conditional proposition corresponding to a merely apparent inference. Propositions and inferences which are not verbal or merely apparent are real.

Mill argues that not only mathematics but logic itself contains real inferences. To demonstrate this he embarks on a semantic analysis of sentences and terms (he calls them 'propositions' and 'names'), of syllogistic logic and of the so-called 'Laws of Thought'. His analysis has imperfections and he does not unify it in a fully general account, but he supplies the foundations of such an account, and in doing so takes the empiricist epistemology of logic and mathematics to a new level.

The starting point is a distinction between the denotation and connotation of names. Names, which may be general or singular, denote things and connote attributes of things. A general name connotes attributes and denotes each object which has those attributes. Most singular names also connote attributes.

There is, however, an important class of singular names – proper names in the ordinary sense, such as 'Dartmouth' – which denote an object without connoting any property (see PROPER NAMES). Identity propositions which contain only non-connotative names, such as 'Tully is Cicero', are verbal, in Mill's view. They lack content in the sense that, according to Mill, the only information conveyed is about the names themselves: 'Tully' denotes the same object as 'Cicero' does. Mill's point is that there is no fact in the world to which 'Cicero is Tully' corresponds. But to class these propositions as verbal would require a change in the characterization of verbal propositions given above. Moreover, knowledge that Cicero is Tully is not a priori. We cannot know the proposition to be true just by reflecting on the meaning of the names – whereas Mill's overall intention is that the class of verbal propositions should be identical with the class of propositions which are innocuously a priori *because* they are empty of content. He does not comment on these difficulties.

The meaning of a declarative sentence – 'the import of a proposition' – is determined by the connotation, not the denotation, of its constituent names; the sole exception being connotationless proper names, where meaning is determined by denotation. (Again Mill does not explain how this thesis about the meaning of proper names is to be reconciled with the a posteriority of 'Cicero is Tully'.) Mill proceeds to show how the various syntactic forms identified by syllogistic theory yield conditions of truth for sentences of those forms, when the connotation of their constituent names is given.

Armed with this analysis he argues that logic contains real inferences and propositions. He assumes that to assert a conjunction, 'A and B', is simply to assert A and to assert B. He defines 'A or B' as 'If not A, then B, and if not B, then A'. 'If A then B' means, he thinks, 'The proposition B is a legitimate inference from the proposition A'. From these claims it follows that certain deductive inferences, for example, from a conjunction to one of its conjuncts, are merely apparent. But, Mill holds, the laws of contradiction and excluded middle are real – and therefore a posteriori – propositions. He takes it that 'not P' is equivalent in meaning to 'It is false that P'; if we further assume the equivalence in meaning of P and 'It is true that P', the principle of contradiction becomes, as he puts it, 'the same proposition cannot at the same time be false and true'. 'I cannot look upon this', he says, 'as a merely verbal proposition'. He makes analogous remarks about excluded middle, which turns – on these definitions – into the principle of bivalence: 'Either it is true that P or it is false that P'.

Mill adds an epistemological argument to this semantic analysis. If logic did not contain real inferences, all deductive reasoning would be a *petitio principii*, a begging of the question, and could produce no new knowledge. Yet clearly it does produce new knowledge. So logic must contain real inferences.

Unfortunately, Mill mixes up this epistemological argument with an interesting but distinct objective. He wants to show that 'all inference is from particulars to particulars', in order to demystify the role that general propositions play in thought. He argues that in principle they add nothing to the force of an argument; particular conclusions could always be derived inductively direct from particular premises. Their value is psychological. They play the role of 'memoranda' or summary records of the inductive potential of all that we have observed, and they facilitate 'trains of reasoning' (for example, as in 'This is A; All As are Bs; No Bs are Cs; so this is not C'). Psychologically they greatly increase our memory and reasoning power, but epistemologically they are dispensable.

This thesis is connected to Mill's rejection of 'intuitive' knowledge of general truths and to his inductivism (see §5 below). But there is also a deeper way in which a radical empiricist must hold that all inference is from particulars to particulars. For consider the inference from 'Everything is F' to 'a is F'. Is it a real or merely apparent inference? It is impossible to hold it real if one also wishes to argue that real inferences are a posteriori. But the only way in which Mill can treat it as verbal is to treat the premise as a conjunction: 'a is F and b is F and . . .'. If that approach is precluded, then all that remains is to deny that 'Everything is F' is propositional – it must, rather, express an inferential commitment. Both approaches are very close to the surface in Mill's discussion of the syllogism, though neither emerges clearly.

3 Mathematics

The strategy which Mill applies to mathematics is broadly similar to his approach to logic. If it was merely verbal, mathematical reasoning would be a *petitio principii*, but semantic analysis shows that it contains real propositions.

Mill provides brief but insightful empiricist sketches of geometry and arithmetic. The theorems of geometry are deduced from premises which are real propositions inductively established. (Deduction is itself largely a process of real inference.) These premises, where they are not straightforwardly true of physical space, are true in the limit. Geometrical objects – points, lines, planes – are ideal or 'fictional' limits of ideally constructible material entities. Thus the real empirical assertion underlying an axiom such as 'Two straight lines cannot enclose a space' is something like 'The more closely two lines approach absolute breadthlessness and straightness, the smaller the space they enclose'.

Applying his distinction between denotation and connotation, Mill argues that arithmetical identities such as 'Two plus one equals three' are real propositions. Number terms denote 'aggregates' and connote certain attributes of aggregates. (He does not say that they denote those attributes of the aggregates, though perhaps he should have done.) 'Aggregates' are natural, not abstract, entities – 'collections' or 'agglomerations' individuated by a principle of aggregation. This theory escapes some of the influential criticisms Frege later made of it, but its viability none the less remains extremely doubtful. The respects in which aggregates have to differ from sets if they are to be credibly natural, and not abstract, entities are precisely those in which they seem to fail to produce a fully adequate ontology for arithmetic. (One can, for example, number numbers, but can there be aggregates of aggregates, or of attributes of aggregates, if aggregates are natural entities?)

However this may be, Mill's philosophical programme is clear. Arithmetic, like logic and geometry, is a natural science, concerning a category of the laws of nature – those concerning aggregation. The fundamental principles of arithmetic and geometry, as well as of logic itself, are real. Mill provides the first thoroughly empiricist analysis of meaning and of deductive reasoning itself.

He distinguishes his view from three others – 'Conceptualism', 'Nominalism' and 'Realism'.

'Conceptualism' is his name for the view which takes the objects studied by logic to be psychological states or acts. It holds that names stand for 'ideas' which make up judgments and that 'a proposition is the expression of a relation between two ideas'. It confuses logic and psychology by assimilating propositions to judgments and attributes of objects to ideas. Against this doctrine Mill insists that:

> All language recognizes a difference between doctrine or opinion, and the fact of entertaining the opinion; between assent, and what is assented to . . . . Logic, according to the conception here formed of it, has no concern with the nature of the act of judging or believing; the consideration of that act, as a phenomenon of the mind, belongs to another science.
>
> (*System of Logic*)

The Nominalists – Mill cites Hobbes – hold that logic and mathematics are entirely verbal. Mill takes this position much more seriously than Conceptualism and seeks to refute it in detail. His main point is that Nominalists are only able to maintain their view because they fail to distinguish between the denotation and the connotation of names, 'seeking for their meaning exclusively in what they denote' (*System of Logic*) (see NOMINALISM).

Nominalists and Conceptualists hold that logic and mathematics can be known non-empirically, while yet retaining the view that no real proposition about the world can be so known. Realists hold that logical and mathematical knowledge is knowledge of universals which exist in an abstract Platonic domain; the terms that make up sentences being signs that stand for such universals. Versions of this view were destined to stage a major revival in philosophy, and semantic analysis would be their main source, but it is the view Mill takes least seriously.

In the contemporary use of the term, Mill is himself a nominalist – he rejects abstract entities (see ABSTRACT OBJECTS). However, just as severe difficulties lie in the way of treating the ontology of arithmetic in terms of aggregates rather than sets, so there are difficulties in treating the ontology of general semantics without appealing to universals and sets, as well as to natural properties and objects. We can have no clear view of how Mill would have responded to these difficulties had they been made evident to him. But we can be fairly sure that he would have sought to maintain his nominalism.

However, his main target is the doctrine that there are real a priori propositions (see A PRIORI). What, he asks, goes on in practice when we hold a real proposition to be true a priori? We find its negation inconceivable, or that it is derived, by principles whose unsoundness we find inconceivable, from premises whose negation we find inconceivable. Mill is not offering a definition of what is meant by such terms as 'a priori', or 'self-evident'; his point is that facts about what we find inconceivable are all that lends colour to the use of these terms.

They are facts about the limits, felt by us from the inside, on what we can imagine perceiving. Mill thought he could explain these facts about unthinkability, or imaginative unrepresentability, in associationist terms, and much of his work claims to do so. This associationist psychology is unlikely nowadays to convince, but that does not affect his essential point: the step from our inability to represent to ourselves the negation of a proposition, to acceptance of its truth, calls for justification. Moreover, the justification itself must be a priori if it is to show that the proposition is known a priori.

4 'Psychologism' and naturalism

Mill is often mistakenly accused of 'psychologism' in his treatment of logic – an accusation which seems to go back to HUSSERL (and one which Frege does not make). 'Psychologism' is the view that laws of logic are psychological laws concerning our mental processes; or that 'meanings' are mental entities, and that 'judgments' assert relationships among these entities. But Mill's view, as we have seen, is that logic and mathematics are the most general empirical sciences, governing *all* phenomena. He explicitly holds that the distinction between necessary and contingent truths, understood 'metaphysically', is empty. And he dismisses the Conceptualist claim that names refer to ideas and propositions express or assert a psychological relation between them.

What explains, then, the attribution of 'psychologism' to Mill? Husserl quotes a passage from *An Examination of Sir William Hamilton's Philosophy* (1865), which has been cited many times since:

> Logic is not the theory of Thought as Thought, but of valid Thought; not of thinking, but of correct thinking. *It is not a Science distinct from, and coordinate with Psychology. So far as it is a science at all, it is a part, or branch, of Psychology; differing from it, on the one hand as the part differs from the whole, and on the other, as an Art differs from a Science. Its theoretic grounds are wholly borrowed from Psychology, and include as much of that science as is required to justify the rules of the art.*
>
> (italics show portion quoted by Husserl)

To give this a psychologistic reading is to take it out of context. Mill means that the logician must formulate rules of reasoning in a manner which will be as helpful as possible to inquirers, and must draw on the psychology of thought to do so. It is in that sense that the art of the logician borrows from the science of the psychologist. How best to promote the art of clear thinking is a psychological question. None the less,

> the laws, in the scientific sense of the term, of Thought as Thought – do not belong to Logic, but to Psychology: and it is only the *validity* of thought which Logic takes cognizance of.
>
> (Mill, *Hamilton's Philosophy*)

So it is wrong to accuse Mill of psychologism about logic. But there is a sense in which his view of our most basic forms of inductive reasoning is psychologistic, or naturalistic. For how does he respond to the Kantian claim that the very possibility of knowledge requires that there be a priori elements in our knowledge? Even if we accept his inductive account of logic and mathematics, must we not accept the principle of induction itself as a priori?

For Mill, the primitive form of reasoning – in both the epistemological and the aetiological sense – is enumerative induction, the disposition to infer that all As are B from the observation of a number of As which are all B. (Or to the conclusion that a given percentage of all As are B from the observation of that percentage of Bs among a number of As.) We spontaneously agree in reasoning that way, and in holding that way of reasoning to be sound. This method of reasoning, enumerative induction, is not a merely verbal principle. So it cannot on Mill's own account be a priori. Mill says that we learn 'the laws of our rational faculty, like those of every other natural agency', by 'seeing the agent at work'. We bring our most basic reasoning dispositions to self-consciousness by critical reflection on our actual practice. He is right to say that this reflective scrutiny of practice is, in a *certain* sense, an a posteriori process. It examines dispositions which we have before we examine them. Having examined our dispositions, we reach a reflective equilibrium in which we endorse some – and perhaps reject others. We endorse them as sound norms of reasoning. There is nothing more to be said: no further story, platonic or transcendental, to be told.

Unlike Hume, or even Reid, Mill shows no interest at all in scepticism. If one thinks that scepticism is both unanswerable and unserious this may be true philosophic wisdom. But to Mill's epistemological critics, whether they were realists or post-Kantian idealists, it seemed obvious that it was evasion, not wisdom. Naturalism could only seem to differ from scepticism by being uncritical, and in this we find the truth in the allegation that Mill's system of logic is 'psychologistic'; if it is sound criticism, it is sound criticism of all naturalistic epistemology.

5 Inductive science

Mill does not raise purely sceptical questions about simple generalization from experience; he none the less thinks it a highly fallible method. His aim is to show how reasoning methods can evolve from it which greatly reduce the fallibility of induction, even though they can never wholly eliminate it.

Humankind begins with 'spontaneous' and 'unscientific' inductions about particular unconnected natural phenomena or aspects of experience. As these generalizations accumulate and interweave, they justify the second-order inductive conclusion that *all* phenomena are subject to uniformity, and more specifically, that all have discoverable sufficient conditions. In this less vague form, the principle of general uniformity becomes, given Mill's analysis of causation, the Law of Universal Causation. It in turn provides (Mill believes) the grounding assumption for a new style of reasoning about nature – eliminative induction.

In this type of reasoning, the assumption that a type of phenomenon has uniform causes, together with a (revisable) assumption about what its possible causes are, initiates a comparative inquiry in which the actual cause is identified by elimination. Mill formulates the logic of this eliminative reasoning in his well-known 'Methods of Experimental Inquiry' (Chapter 7, Book 2 of *System of Logic*). His picture of the interplay between enumerative and eliminative reasoning, and of the way it entrenches, from within, our rational confidence in the inductive process, is elegant and penetrating.

The improved scientific induction which results from this new style of reasoning spills back onto the principle of Universal Causation on which it rests, and raises its certainty to a new level. That in turn raises our confidence in the totality of particular enumerative inductions from which the principle is derived. So the amount of confidence with which one can rely on the 'inductive process' as a whole depends on the point which has been reached in its history – though the confidence to be attached to particular inductions always remains variable.

Mill's inductivism – his view that enumerative induction is the only ultimately authoritative method of inference to new truths – was rejected by William WHEWELL, who argued that the really

fundamental method in scientific inquiry was the Hypothetical Method, in which one argues to the truth of a hypothesis from the fact that it would explain observed phenomena (see INFERENCE TO THE BEST EXPLANATION). Mill had read Whewell's *History of the Inductive Sciences* (1837), and could hardly fail to be aware of the pervasiveness of hypotheses in the actual process of inquiry, or of their indispensability in supplying working assumptions – their 'heuristic' value, as Whewell called it. But what Mill could not accept was that the mere fact that a hypothesis accounted for the data in itself provided a reason for thinking it true.

Yet Whewell's appeal was to the actual practice of scientific reasoning, as observed in the history of science. An appeal of that kind was precisely what Mill, on his own principles, could not ignore. If the disposition to hypothesize is spontaneous, why should it not be recognized as a fundamental method of reasoning to truth, as enumerative induction is?

Mill's refusal to recognize it is not arbitrary. The essential point underlying it is a powerful one: it is the possibility that a body of data may be explained equally well by more than one hypothesis. Mill does not deny the increasingly deductive and mathematical organization of science – he emphasizes it. That is quite compatible with his inductivism, and indeed is central to his account of the increasing reliability of the inductive process. He further agrees that a hypothesis can sometimes be shown, by eliminative methods of inductive reasoning which he accepts, to be the only one consistent with the facts. And he allows various other cases of apparently purely hypothetical reasoning which are, in his view, genuinely inductive.

When all such cases have been taken into account, we are left with pure cases of the Hypothetical Method, in which the causes postulated are not directly observable, and not simply because they are assumed to operate – in accordance with known laws, inductively established – in regions of time or space too distant to observe. What are we to say of such hypotheses? For example of the 'undulatory' theory of light? They cannot, Mill says, be accepted as inductively established truths, not even as probable ones.

> An hypothesis of this kind is not to be received as probably true because it accounts for all the known phenomena; since this is a condition sometimes fulfilled tolerably well by two conflicting hypotheses; while there are probably many others which are equally possible, but which from want of anything analogous in our experience, our minds are unfitted to conceive.
>
> (*System of Logic*)

Such an hypothesis can suggest fruitful analogies, Mill thinks, but cannot be regarded as yielding a new truth itself. The data do not determine a unique hypothesis: it is this possibility of underdetermination which stops him from accepting hypothetical reasoning as an independent method of achieving truth.

In seeing the difficulty Mill is certainly on solid ground. What he does not see, however, is how much must be torn from the fabric of our belief if inductivism is applied strictly. So it is an important question whether the difficulty can be resolved – and whether it can be resolved within a naturalistic framework which does not appeal to an underlying idealism, as Whewell did. If naturalism can endorse the hypothetical method, then among other things it can develop a more plausible empiricism about logic and mathematics than Mill's. But the ramifications of his inductivism are even wider, as becomes apparent from an examination of his general metaphysics.

6 Mind and matter

Mill sets out his metaphysical views in *An Examination of Sir William Hamilton's Philosophy.* Hamilton was the last eminent representative of the Scottish Common Sense School, and a ferocious controversialist – in Mill's eyes a pillar of the right-thinking establishment, ripe for demolition. The result is that Mill's discussion of general metaphysical issues is cast in a highly polemical form which leaves important issues shrouded in obscurity. He does however give himself space to develop his view of our knowledge of the external world.

He begins with a doctrine which he rightly takes to be generally accepted (in his time) on all sides: 'that all the attributes which we ascribe to objects, consist in their having the power of exciting one or another variety of sensation in our minds; that an object is to us nothing else than that which affects our senses in a certain manner' (*Hamilton's Philosophy*). This is 'the doctrine of the Relativity of Knowledge to the knowing mind'. It makes epistemology, in Mill's words, the 'Interpretation of Consciousness'. He proceeds to analyse what we mean when we say that objects are external to us:

> We mean, that there is concerned in our perceptions something which exists when we are not thinking of it; which existed before we had ever thought of it, and would exist if we were annihilated; and further, that there exist things which we never saw, touched or otherwise perceived, and things which have never been perceived by man. This idea of something which is distinguished from our

> fleeting impressions by what, in Kantian language, is called Perdurability; something which is fixed and the same, while our impressions vary; something which exists whether we are aware of it or not, constitutes altogether our idea of external substance. Whoever can assign an origin to this complex conception, has accounted for what we mean by the belief in matter.
>
> (*Hamilton's Philosophy*)

To assign this origin Mill postulates that

> we are capable of forming the conception of Possible sensations; sensations which we are not feeling at the present moment, but which we might feel, and should feel if certain conditions were present.
>
> (*Hamilton's Philosophy*)

> These possibilities, which are conditional certainties, need a special name to distinguish them from mere vague possibilities, which experience gives no warrant for reckoning upon. Now, as soon as a distinguishing name is given, though it be only to the same thing regarded in a different aspect, one of the most familiar experiences of our mental nature teaches us, that the different name comes to be considered as the name of a different thing.
>
> (*Hamilton's Philosophy*)

Physical objects are 'Permanent Possibilities of Sensation' (There is a change in the 'permanent' possibilities of sensation whenever there is change in the world. Mill also uses other terms, such as 'certified' or 'guaranteed'.) We often find that whenever a given cluster of certified possibilities of sensation obtains, then a certain other cluster follows. 'Hence our ideas of causation, power, activity... become connected, not with sensations, but with groups of possibilities of sensation' (*Hamilton's Philosophy*) (see PHENOMENALISM).

However, even if our notion of matter as the external cause of sensations can be explained on psychological principles, it is still possible to hold that good grounds can be given for thinking the notion to have instances. There might be a legitimate inference from the existence of the permanent possibilities and their correlations to the existence of an external cause of our sensations. It is at just this point that Mill's inductivism plays a part. The inference would be a case of hypothetical reasoning, to an explanation of experience which transcended all possible data of experience; and that is precisely what Mill rejects: 'I assume only the tendency, but not the legitimacy of the tendency, to extend all the laws of our own experience to a sphere beyond our experience' (*Hamilton's Philosophy*).

If matter is the permanent possibility of sensation what is mind? Can it also be resolved into 'a series of feelings, with a background of possibilities of feeling'? Mill finds in this view a serious difficulty: to remember or expect a state of consciousness is not simply to believe that it has existed or will exist; it is to believe that *I myself* have experienced or will experience that state of consciousness.

> If, therefore, we speak of the Mind as a series of feelings, we are obliged to complete the statement by calling it a series of feelings which is aware of itself as past and future; and we are reduced to the alternative of believing that the Mind, or Ego, is something different from any series of feelings, or possibilities of them, or of accepting the paradox, that something which *ex hypothesi* is but a series of feelings, can be aware of itself as a series.
>
> (*Hamilton's Philosophy*)

Thus although Mill is unwilling to accept 'the common theory of Mind, as a so-called substance', the self-consciousness involved in memory and expectation drives him to 'ascribe a reality to the Ego – to my own Mind – different from that real existence as a Permanent Possibility, which is the only reality I acknowledge in Matter' (*Hamilton's Philosophy*).

This ontology, Mill thinks, is consistent with common sense realism about the world. Phenomenalism – the conception of matter as possibility of experience – allegedly leaves common sense and science untouched. In particular, mind and experience is still properly seen as a part of the natural order.

Yet if phenomenalism is right, only the experiences are real. Mill thinks we are led to that conclusion by the very standards of reasoning recognized in a naturalistic 'science of science', or 'system of logic'. If he is right, then the naturalistic vision of the world which sees minds as part of a larger causal order is self-undermining. For if we are led to the conclusion that only states of consciousness are real by *an application of naturalism's own standards*, then that conclusion has to be understood on the same level as the naturalistic affirmation that states of consciousness are themselves part of a larger causal order external to them – and therefore as inconsistent with it. Causal relations cannot exist between fictional entities which are mere markers for possibilities of sensation.

This is the fault-line in Mill's epistemology and metaphysics. Either naturalism undermines itself, or there is something wrong with Mill's inductivist

analysis of our natural norms of reasoning, or with his endorsement of the doctrine of the Relativity of Knowledge, or with both. It is not obvious that Mill's most fundamental tenet – his naturalistic view of the mind – can be safeguarded by rejecting inductivism and endorsing the hypothetical method. There is still something implausible about hypothesizing the world as an explanation of pure experience. Mill himself explicitly acknowledged that memory, as well as induction, has epistemic authority. Had he analysed the significance of such an acknowledgment more thoroughly, he might have noted a parallel: on the one hand a primitive epistemic norm which warrants assertions about the past based on present memory-experiences; on the other, primitive epistemic norms which warrant assertions about the physical world based on perceptual experience. But perhaps that would have taken him too far in the direction of Reid's principles of common sense.

7 Freedom and the moral sciences

The sixth and last book of the *System of Logic* is a classical statement of methodology in the 'moral' sciences (that is, the human sciences). Its strength derives partly from the fact that Mill was a philosopher who also practised the whole range of these sciences as they then stood. He was mainly known as a political economist, but had strong interests in psychology and in the nascent science of sociology. He thought as an economist as well as a philosopher about socialism, taxation and systems of property, and he thought in sociological terms about such topics as democracy and the role of moral and intellectual elites. He also took an interest in a variety of psychological topics, including desire, pleasure and will, and the origins of conscience and justice.

The phenomena of mind and society are, in Mill's view, causal processes. If mind and society are part of the causal order, and causation is regular succession, then the general model of explanation he has proposed, according to which explanation subsumes facts under laws linking them to their causal antecedents, will apply, he thinks, to the moral sciences. It may be hard for moral science to live up to it, in view of the complexity of its data, but the model stands as an ideal. Important issues remain about the character of and relationships between the various moral sciences, and Mill treats these issues in detail. But he does not think that the very idea of a moral science raises new metaphysical or epistemological problems (see Explanation in history and social science).

Psychological concepts are intentional and, correspondingly, the moral sciences are interpretative. Can laws of individual behaviour be formulated, as Mill assumed, in this interpretative vocabulary? His analysis of the moral sciences takes their fundamental laws to lie in the domain of psychology. He was familiar with a different view, that of Auguste Comte, who held that the fundamental and irreducible moral science was sociology (a term coined by Comte). There was no deeper moral science, no science of psychology; the next level below sociology was the physical science of biology. Mill rejected that view, but enthusiastically shared Comte's vision of a historical sociology. Psychology may be the irreducible theoretical basis of the moral sciences; historical sociology is to be, as far as Mill was concerned, their prime exhibit.

Associationism and a Comtean historical sociology are thus the driving ideas in Mill's logic of the moral sciences. They interlock. Associationism fortifies his belief in the mutability of human nature: different social and historical formations can build radically different patterns of association. The bridge between historical sociology and the invariant laws of associationist psychology can be provided, Mill thinks, by an innovation of his own: a science he calls 'Ethology', which will study the different forms of human character in different social formations. He intended to write a treatise on the subject; significantly, he failed.

How, on this naturalistic view of mind and society, can human beings be free? The question mattered deeply to Mill. The conclusion others drew from the doctrine of determinism, namely, that we have (in Mill's phrase) no 'power of *self*-formation', and hence are not really responsible for our character or our actions, would have destroyed his moral vision. Self-formation is the fulcrum of his ideal of life, and 'moral freedom', the ability to bring one's desires under the control of a steady rational purpose, is a condition of self-formation, of having a character in the full sense (see Free will §§3–4).

Thus Mill had to show how causally conditioned natural objects can also be morally free agents. The sketch of a solution in the *System of Logic* (Book 6, ch. 2), which Mill thought the best chapter in the book, is brief but penetrating. (There is a longer discussion in *An Examination of Sir William Hamilton's Philosophy*, ch. 26.) One of its leading features is a distinction between resistible and irresistible causes; 'in common use', only causes which are 'irresistible', whose operation is 'supposed too powerful to be counteracted at all', are called necessary:

> There are physical sequences which we call necessary, as death for want of food or air;

> there are others which, though as much cases of causation as the former, are not said to be necessary, as death from poison, which an antidote, or the use of the stomach-pump, will sometimes avert . . . human actions are in this last predicament: they are never (except in some cases of mania) ruled by any one motive with such absolute sway, that there is no room for the influence of another.
>
> (*System of Logic*)

An action caused by an irresistible motive (a 'mania') is plainly not free. This is certainly very pertinent. Yet something is added when we move from the idea of motives being resistible by other motives to the idea of moral freedom, the idea that *I* have the power to resist motives. It is the ability to recognize and respond to reasons. I act freely if I could have resisted the motive on which I in fact acted, had there been good reason to do so. A motive impairs my moral freedom if it cannot be defeated by a cogent reason for not acting on it. Mill fails to bring this connection between freedom and reason into clear view, but he relies on it in his ethical writings. He takes it that I am more or less free overall, according to the degree to which I can bring my motives under scrutiny and act on the result of that scrutiny. So I can *make* myself more free, by shaping desires or at least cultivating the strength of will to overcome them.

> A person feels morally free who feels that his habits or his temptations are not his masters, but he theirs: who even in yielding to them knows that he could resist . . . we must feel that our wish, if not strong enough to alter our character, is strong enough to conquer our character when the two are brought into conflict in any particular case of conduct. And hence it is said with truth, that none but a person of confirmed virtue is completely free.
>
> (*System of Logic*)

The identification of moral freedom with confirmed virtue, and (less explicitly) of confirmed virtue with steady responsiveness to reasons, is present in Mill as in Kant (see KANT, I. §11). But Mill does not address crucial questions such as what is it to grasp a reason, or how reason can be efficacious. To vindicate the coherence of his view one would have to show how to answer such questions in a way which is compatible with naturalism. The problem remains central in contemporary philosophy – certainly Mill himself never took full stock of it.

8 Happiness, desire and will

Mill's single ultimate standard of theoretical reason is enumerative induction. His single ultimate standard of practical reason is the principle of utility; its standard is the good of all. But what is the good? According to Mill, it is happiness, understood as 'pleasure, and freedom from pain' (*Utilitarianism*: ch. 5) (see HAPPINESS). His case rests on the following principle of method:

> The sole evidence it is possible to produce that anything is desirable, is that people do actually desire it. If the end which the utilitarian doctrine proposes to itself were not, in theory and in practice, acknowledged to be an end, nothing could ever convince any person that it was so.
>
> (*Utilitarianism*: ch. 5)

Mill is not claiming that the conclusion that happiness is desirable follows deductively from the premise that people in general desire it. He gives some ground for that misinterpretation when he compares the move from 'desired' to 'desirable' to those from 'seen' and 'heard' to 'visible' and 'audible'. Nevertheless, his procedure is simply an appeal to reflective practice, just as in the case of enumerative induction – where again the 'sole evidence' that enumerative induction is an ultimate norm of reasoning is that we acknowledge it as such 'in theory and in practice'.

However, a question which is appropriate by Mill's own principle of method is whether reflective practice shows that happiness is the *only* thing we desire. Do not human beings, in theory and in practice, desire things other than happiness? Mill anticipates this question and responds to it at length. He claims that when we want a particular object for its own sake and with no further end in view we desire it because we think of it as enjoyable: 'to desire anything, except in proportion as the idea of it is pleasant, is a physical and metaphysical impossibility' (*Utilitarianism*: ch. 5). But this does not mean that we desire all objects as *means* to our pleasure. The desire for an object is genuinely a desire for that *object*; it is not the desire for pleasure as such. Mill's way of marking this is to say that the object is desired as a 'part' or an 'ingredient' of happiness, not as a means to it. His rejection of psychological egoism was one of the points on which he took himself to be at odds with Bentham (see BENTHAM, J.). When a person does something because they think it will be pleasant – for example a generous person who gives a present – it does not follow that they are acting selfishly (see EGOISM AND ALTRUISM). Generous people take pleasure in

the prospect of giving, not in the prospect of getting pleasure; their desire to give is not derived from the desire to get pleasure. Giving is a part of their happiness, not a means to it.

Thus Mill's case for the claim that happiness is the sole human end, put more carefully, is this: 'Whatever is desired otherwise than as a means to some end beyond itself, and ultimately to happiness, is desired as itself a part of happiness, and is not desired for itself until has become so' (*Utilitarianism*: ch. 5). Nothing here assumes Hume's view that every action must ultimately flow from an underived desire. That is a quite separate issue, and Mill's view of it is closer to that of Kant or Reid than to that of Hume. He insists 'positively and emphatically':

> that the will is a different thing from desire; that a person of confirmed virtue, or any other person whose purposes are fixed, carries out his purposes without any thought of the pleasure he has in contemplating them, or expects to derive from their fulfilment.
>
> (*Utilitarianism*: ch. 5)

This distinction between purpose and desire is central to Mill's conception of the will. When we develop purposes we can will against mere likings or aversions: 'In the case of an habitual purpose, instead of willing the thing because we desire it, we often desire it only because we will it' (*Utilitarianism*: ch. 5). Every action is caused by a motive, but not every motive is a liking or aversion:

> When the will is said to be determined by motives, a motive does not mean always, or solely, the anticipation of a pleasure or of a pain . . . . A habit of willing is commonly called a purpose; and among the causes of our volitions, and of the actions which flow from them, must be reckoned not only likings and aversions, but also purposes.
>
> (*System of Logic*)

The formation of purposes from desires is the evolution of will; it is also the development of character. Mill quotes Novalis: 'a character is a completely fashioned will' (*System of Logic*). Not that this reflects the whole of his view of character; character for him requires the cultivation of feeling as well as the cultivation of will: 'A person whose desires and impulses are his own – are the expression of his own nature, as it has been developed and modified by his own culture – is said to have a character' (*On Liberty*). Developed spontaneity of feeling is part of fully-perfected character, but certainly moral freedom is too – 'none but a person of confirmed virtue is completely free'. As noted in §7 above, Mill does not address the crucial question of what it is for a purpose to be informed by reason. Still, the distinction between purpose and desire does allow him to recognize conscientious action, action which flows not from any inclination but solely from a habit of willing; he asserts the possibility and value of a 'confirmed will to do right' (*Utilitarianism*: ch. 5), distinct from motives of anticipated pleasure and pain. That 'virtuous will', however, is not for him an intrinsic good, as it is for Kant. It is:

> a means to good, not intrinsically a good; and does not contradict the doctrine that nothing is good to human beings but in so far as it is either itself pleasurable, or a means of attaining pleasure or averting pain.
>
> (*Utilitarianism*: ch. 5)

9 Qualities of pleasure

Happiness – pleasure and the absence of pain – is the sole final end of life. But Mill's idea of it is altogether more romantic and liberal than that of earlier utilitarians. He takes into account the fact that a variety of notions – for example, purity, elevation, depth, refinement and sublimity, and their opposites – enter into our assessments of pleasure. We do not assess pleasures along a single dimension. In his general ethical and political writing, Mill freely draws on that extensive and flexible language. He sees the need to recognize it also in utilitarian theory, but here he does so rather more mechanically by distinguishing 'quality' and 'quantity' of pleasure. From the first publication of *Utilitarianism*, at least three sorts of question have been asked about this famous distinction. The first is whether it is reconcilable with hedonism. The second is epistemological: is there a cogent way of establishing that some pleasures are superior in 'quality'? The third question, perhaps the most challenging, though less often discussed, is how the distinction fits into the framework of utilitarianism.

As to the first question: there is indeed, as Mill says, no reason in logic why more than one characteristic of pleasures should not be relevant to estimating their value – though if we call those characteristics 'quantity' and 'quality' we need to maintain a careful distinction between the quantity and quality of a pleasure on the one hand and its degree of value on the other. All that hedonism requires is that the only things that make a pleasure valuable are its characteristics as a *pleasure* (see HEDONISM).

Nevertheless, an impression lingers that Mill's discussion appeals to intuitions which are not hedonistic. For example:

> Few human creatures would consent to be changed into any of the lower animals, for a promise of the fullest allowance of a beast's pleasures; no intelligent human being would consent to be a fool, no instructed person would be an ignoramus, no person of feeling and conscience would be selfish and base, even though they should be persuaded that the fool, the dunce, or the rascal is better satisfied with his lot than they are with theirs.
>
> (*Utilitarianism*: ch. 5)

He also notes that a 'being of higher faculties requires more to make him happy, is capable probably of more acute suffering, and is certainly accessible to it at more points, than one of an inferior type' (*Utilitarianism*: ch. 5). So a being of higher faculties may be faced with a choice: on the one hand a life of acute suffering, with no access to any of the higher pleasures which its faculties make it capable of appreciating, on the other, a cure (for example, an operation) which relieves its suffering but leaves it only with the pleasures available to a fool or a dunce. Is Mill saying that in *all* such cases the life of suffering should be preferred? He does not say so explicitly and if he does adhere to hedonism he should not. For cases are surely possible in which life after the cure offers a stream of pleasures more valuable overall, taking quality as well as quantity into account, than the life of suffering in which one retains one's higher faculties but is bereft of higher pleasures.

What of the epistemological question? Mill compares assessments of the comparative quality of pleasures to assessments of their comparative quantity: both are determined by 'the feelings and judgments of the experienced' (*Utilitarianism*: ch. 5). But a judgment that the pleasure derived from film A is of a higher kind than that derived from watching film B is clearly, as Mill conceives it, an evaluative judgment. The proper comparison would have been with the evaluative judgment that pleasure as such is desirable. A higher pleasure has some feature, *qua* pleasure, that makes it more desirable overall than a lower pleasure of like quantity. And Mill could have said that with this judgment, as with basic evaluative judgments in general, the only criterion is reflective practice – self-examination and discussion. In such discussion, some people emerge as better judges than others – this is not a circularity but an inherent feature of normative judgment.

Yet now the third question becomes pressing: how are such judgments of the quality of pleasures to be registered in the utilitarian calculus? In requiring utilitarianism to take them into account Mill makes a move of political as well as ethical significance. For what rank do we give to these pleasures in our social ordering – the rank which highly developed human natures attach to them or that which lower human natures attach to them? Mill's answer is unambiguous: it is the verdict of 'competent judges' which stands.

Suppose that beings of highly developed faculties place the pleasures of scientific discovery or artistic creation so much higher than those of material well-being that (above a certain modicum of physical comfort and security) any amount of the former, however small, is ranked by them above any amount of the latter, however large. Suppose, however, that beings of considerably less developed faculties would not share this assessment. And now suppose that the question is put to Mill, how much of the lower pleasure of the less developed being may be sacrificed to maintain the more highly developed being's higher pleasure? Mill's view is that the more highly developed being delivers the correct assessment of the relative value of the higher and lower pleasures. But, by hypothesis, it would be prepared to sacrifice any amount of the lower pleasure, down to a modicum of physical comfort and security, for the smallest amount of the higher. Must the same hold for the interpersonal case? Must it be correct for the utilitarian to sacrifice any amount of the lower pleasures of lower beings, down to a level at which they are provided with the modicum of comfort and security, in order to secure some higher pleasure for a higher being? Mill provides no answer.

10 The utility principle

Though Mill deepened the utilitarian understanding of pleasure, desire, character and will, he never adequately re-examined the principle of utility itself. When he states the utilitarian doctrine before considering what kind of proof can be given of it, he states it thus: 'Happiness is desirable, and the only thing desirable, as an end, all other things being only desirable as means to that end' (*Utilitarianism*: ch. 5). In effect, he takes his task to be that of demonstrating the truth of hedonism. All he has to say about the move from hedonism to the utility principle is that if 'each person's happiness is a good to that person' then 'the general happiness' must be 'a good to the aggregate of all persons'. In a letter in which he explains this unclear remark, he says: 'I merely meant in this particular sentence to argue that since A's happiness is a good, B's a good, C's a good, etc, the sum of all these goods must be a good' (*Later Letters*). This contains two inexplicit assumptions. The more obvious point is that an egoist may accept that Mill has shown that 'each person's happiness is a good to that person', but deny that he has shown

that happiness is a good tout *court*. The egoist denies that Mill has shown that *everyone* has reason to promote the happiness of anyone. That requires a separate postulate, as Henry Sidgwick pointed out.

The second inexplicit assumption is more subtle. At the end of the last chapter of *Utilitarianism*, 'On the Connexion between Justice and Utility', Mill does explain that he takes 'perfect impartiality between persons' to be part of the very meaning of the Greatest Happiness Principle:

> That principle is a mere form of words without rational signification, unless one person's happiness, supposed equal in degree (with the proper allowance made for kind), is counted for exactly as much as another's. Those conditions being supplied, Bentham's dictum, 'everybody to count for one, nobody for more than one', might be written under the principle of utility as an explanatory commentary.
>
> (*Utilitarianism*: ch. 5)

So here Mill supplies the required postulate of impartiality. However, the concept of impartiality does not, on its own, yield utilitarianism's aggregative principle of distribution. Maximizing the *sum* of individuals' happiness, if it makes sense to talk in this way at all, is one way of being impartial: no individual's happiness is given greater weight than any other's in the procedure which determines the value of a state of affairs as a function of the happiness of individuals in that state of affairs. In this sense the procedure implements the principle, 'Everybody to count for one, nobody for more than one'; but so does maximizing the average of all individuals' unweighted happiness. Here too all individuals count for one and no more than one. In fact a wide variety of non-equivalent distributive principles is impartial in this way. The most one could get from combining a postulate of impartiality with hedonism is that ethical value is a positive impartial function of individual happiness and of nothing else. In a footnote to the paragraph Mill glosses the requirement of perfect impartiality as follows: 'equal amounts of happiness are equally desirable, whether felt by the same or by different persons'. That does yield aggregative or average utilitarianism, but it follows neither from the thesis that happiness is the only thing desirable to human beings, nor from the formal notion of impartiality (see IMPARTIALITY).

11 Morality and justice

When we turn to Mill's conception of the relationship between the utility principle and the fabric of principles which regulate everyday social life, we find him again at his most impressive. He stresses that a utilitarian standard of value cannot itself tell what practical rules, aims or ideals we should live by. In his autobiography he dates this conviction to the period of his mental crisis. He now 'gave its proper place, among the prime necessities of human well-being, to the internal culture of the individual' (*Autobiography* 1873). The prime task for human beings was to attend to that internal culture – to develop whatever was best in themselves. The indirect role in which he now cast the utility principle became a fundamental structural feature of his moral and political philosophy. For example, he accuses Auguste Comte of committing:

> the error which is often, but falsely, charged against the whole class of utilitarian moralists; he required that the test of conduct should also be the exclusive motive of it . . . . M. Comte is a morality-intoxicated man. Every question with him is one of morality, and no motive but that of morality is permitted.
>
> (*Auguste Comte and Positivism*)

Mill gives a succinct statement of his own doctrine at the end of the *System of Logic*. As always, he affirms 'that the promotion of happiness is the ultimate principle of Teleology'. But, he continues,

> I do not mean to suggest that the promotion of happiness should be itself the end of all actions, or even of all rules of action. It is the justification, and ought to be the controller, of all ends, but is not itself the sole end . . . . I fully admit that . . . the cultivation of an ideal nobleness of will and conduct, should be to individual human beings an end, for which the specific pursuit either of their own happiness or of that of others (except so far as included in that idea) should, in any case of conflict, give way. But I hold that the very question, what constitutes this elevation of character, is itself to be decided by a reference to happiness as the standard.

The happiness of all is 'the test of all rules of conduct' – and not only rules of conduct but also of cultivation of feelings. How is the test applied? Here Mill learned more from Coleridge than from Bentham; that is, from historical criticism directed at the abstract social visionaries of the Enlightenment. They did not see that moral sentiments can only grow in a stable tradition and social setting. They did not grasp the conditions necessary for such a tradition and setting – education of personal

impulses to a restraining discipline, shared allegiance to some enduring and unquestioned values, 'a strong and active principle of cohesion' among 'members of the same community or state'. Hence:

> They threw away the shell without preserving the kernel; and attempting to new-model society without the binding forces which hold society together, met with such success as might have been anticipated.
>
> (Coleridge)

This feeling for the historicity of social formations and genealogies of morals gives Mill's ethical vision a penetration which is absent from Bentham (and also from the excessively abstract discussions of utilitarianism in twentieth-century philosophy). On the other hand the analysis of morality, rights and justice which Mill fits into this ethical vision owes much to Bentham.

Mill examines the concept of justice in chapter 5 of *Utilitarianism*. Having observed that the idea of something which one may be constrained or compelled to do, on pain of penalty, is central to the idea of an obligation of justice, he notes that it nevertheless 'contains, as yet, nothing to distinguish that obligation from moral obligation in general':

> The idea of penal sanction, which is the essence of law, enters not only into the conception of injustice, but into that of any kind of wrong. We do not call anything wrong, unless we mean to imply that a person ought to be punished in some way or other for doing it; if not by law, by the opinion of his fellow creatures; if not by opinion, by the reproaches of his own conscience.
>
> (*Auguste Comte and Positivism*)

This is a normative, not a positive, account of morality: the morally wrong is that which *ought* to be punished, by law, social opinion or conscience. It would be a circular account if the 'ought' in question were itself a moral 'ought'. But the utility principle is the ultimate principle of 'Teleology'. Teleology is the 'Doctrine of Ends'; 'borrowing the language of the German metaphysicians', Mill also describes it as 'the principles of Practical Reason' (*System of Logic*). So the 'ought' is the 'ought' of Practical Reason – which, making appropriate use of 'laws of nature', produces the 'Art of Life'. Morality itself is only one department of this art. Moral concepts and judgments issue from the moral sentiments, the sentiments involved in guilt and blame; but are corrigible by a rational doctrine of ends. And that doctrine, in Mill's view, is the utility principle.

From this account of morality Mill moves to an account of rights and justice. A person has a moral right to a thing if there is a moral obligation on society to protect them in their possession of that thing. Obligations of justice are distinguished from moral obligations in general by the existence of corresponding rights:

> Justice implies something which it is not only right to do, and wrong not to do, but which some individual person can claim from us as his moral right . . . . Whenever there is a right, the case is one of justice.
>
> (*Auguste Comte and Positivism*)

Upholding rights is one of society's vital tasks. For on it depends our security – which is 'to every one's feelings the most vital of interests':

> This most indispensable of all necessaries, after physical nutriment, cannot be had, unless the machinery for providing it is kept unintermittedly in active play. Our notion, therefore, of the claim we have on our fellow-creatures to join in making safe for us the very groundwork of our existence, gathers feelings around it so much more intense than those concerned in any of the more common cases of utility, that the difference in degree (as is often the case in psychology) becomes a real difference in kind.
>
> (*Auguste Comte and Positivism*)

In this way the claim of justice comes to be felt as a claim of a higher kind than any claim of utility. Justice, Mill concludes:

> is a name for certain classes of moral rules, which concern the essentials of human well-being more nearly, and are therefore of more absolute obligation, than any other rules for the guidance of life.
>
> (*Auguste Comte and Positivism*)

Mill spells out in detail what these moral rules should be in his writings on various social questions. In *Utilitarianism*, he is concerned with the more abstract task of showing how justice-rights take priority over the direct pursuit of general utility by individuals or the state, just as they take priority over the private pursuit of personal ends. His position is thus more complex than that of philosophers in a Kantian tradition who assume, in John Rawls' phrase, that the right (or just) is prior to the good. For Mill, good is philosophically prior to right – but politically and socially right constrains the pursuit of good (see JUSTICE §3).

12 Liberty and democracy

The most celebrated part of Mill's social philosophy, his essay *On Liberty*, must be read in terms of this conception of the right and the good. Mill is not a social contract or 'natural rights' liberal. He appeals instead to 'utility in the largest sense, grounded on the permanent interests of man as a progressive being'. He has in mind the higher human nature, capable of development by self-culture, which he believes to be present in every human being. Self-culture opens access to higher forms of human happiness, but it has to be *self*-culture, first because human potentialities are diverse and best known to each human being itself, and second because only when human beings work to their own plans of life do they develop moral freedom, itself indispensable to a higher human nature.

Given the importance free self-culture thus assumes in Mill's idea of human good, and the account of rights which has just been considered, it will follow that individual liberty must be a politically fundamental right. For self-development is one of 'the essentials of human well-being'. Thus Mill is led to the famous principle enunciated in *On Liberty*:

> the only purpose for which power can be rightfully exercised over any member of a civilized community, against his will, is to prevent harm to others. His own good, either physical or moral, is not a sufficient warrant. He cannot rightfully be compelled to do or forbear because it will be better for him to do so, because it will make him happier, because, in the opinion of others, to do so would be wise, or even right.

A society which respects this principle enables individuals to realize their potential in their own way. It liberates a mature diversity of interest and feeling, and it nurtures the moral freedom of reason and will. Throwing open the gates to talent, creativity and dynamism, it produces the social conditions of moral and intellectual progress. This Millian argument remains the strongest defence of any liberalism founded on teleological ethics. It is a resource upon which teleological liberals will always be able to draw, whether or not they accept Mill's hedonistic conception of the human good or his aggregative conception of the good of all.

However, it is also connected with Mill's ambivalence about democracy. Like many other nineteenth-century thinkers, liberal as well as conservative, Mill felt a deep strain of anxiety about democratic institutions and the democratic spirit (see Democracy §2). Certainly he applauded the end of the *ancien régime* and sympathized with the moral aims of the French Revolution – liberty, equality, fraternity – but from that revolution he also learned, as had the continental liberals, to fear an enemy on the left, as well as an authoritarian enemy on the right. In its revolutionary form the enemy on the left threatened Jacobin terror, or the disasters which attend any attempt to achieve moral ideals by restarting history at year zero. Democracy's settled form, on the other hand, could be observed in the 'democratic republic' of America: a continuous and unremitting pressure towards conforming mediocrity.

The Romantic-Hellenic ideal of human life both inspired Mill's democratic ideals and fuelled his fears about realized democracy. It was an ideal he shared with left Hegelians like Marx, who experienced less difficulty in combining it with democratic egalitarianism. Mill too had a long-term vision in which the emancipation and education of the working class could bring free self-culture to all human beings. He was able to believe, on the basis of his associationist psychology, that all human beings have an equal potential to develop their higher faculties. This warded off the possibility that utilitarianism might recommend an extremely inegalitarian pursuit of higher forms of well-being as the equilibrium state of a fully developed human society.

Thus Mill remained more of a democrat than other liberals of the nineteenth century, such as de Tocqueville or Burckhardt, but like them he saw how moral and cultural excellence and freedom of spirit could be endangered by mass democracy. Like them, his attitude to the immediate prospect of democratic politics was decidedly mixed. What he wanted was a democratic society of freely developed human beings; he did not think it a proximate or certain prospect, and he thought that bad forms of democracy could themselves pose a threat to it by drifting into 'collective despotism' – a danger to which America had already succumbed.

His advice for warding off this threat was not less democracy but more liberty:

> If the American form of democracy overtakes us first, the majority will no more relax their despotism than a single despot would. But our only chance is to come forward as Liberals, carrying out the Democratic idea, not as Conservatives, resisting it.
>
> (*Later Letters*)

This was the importance of the essay on Liberty, and particularly of the defence of liberty of thought and discussion contained therein. Nor were freedom of speech and liberty of the individual the only instruments by which Mill hoped to steer away from bad forms of democracy towards good. Some

of his recommendations – plural voting, a public ballot, a franchise restricted by educational qualification – may now seem misguided or even quaint. Others, including proportional representation of minorities and, not least, his life-long advocacy of equal rights for women, make him seem ahead of his time. At any rate, in political philosophy from Plato's *Republic* to the present day, Mill's discussion of democracy has few rivals – for its open-mindedness, its historical and psychological awareness, and its underlying ethical power.

MĪMĀṂSĀ

The school of Mīmāṃsā or Pūrva Mīmāṃsā was one of the six systems of classical Hindu philosophy. It grew out of the Indian science of exegesis and was primarily concerned with defending the way of life defined by the ancient scripture of Hinduism, the Veda. Its most important exponents, Śabarasvāmin, Prabhākara and Kumārila, lived in the sixth and seventh centuries AD. It was realist and empiricist in orientation. Its central doctrine was that the Veda is the sole means of knowledge of *dharma* or righteousness, because it is eternal. All cognition, it held, is valid unless its cause is defective. The Veda being without any fallible author, human or divine, the cognitions to which it gives rise must be true. The Veda must be authorless because there is no recollection of an author or any other evidence of its having been composed; we only observe that it has been handed down from generation to generation. Mīmāṃsā thinkers also defended various metaphysical ideas implied by the Veda – in particular, the reality of the physical world and the immortality of the soul. However, they denied the existence of God as creator of the world and author of scripture. The eternality of the Veda implies the eternality of language in general. Words and the letters that constitute them are eternal and ubiquitous; it is only their particular manifestations, caused by articulations of the vocal organs, that are restricted to certain times and places. The meanings of words, being universals, are eternal as well. Finally, the relation between word and meaning is also eternal. Every word has an inherent capacity to indicate its meaning. Words could not be expressive of certain meanings as a result of artificial conventions.

The basic orientation of Mīmāṃsā was pragmatic and anti-mystical. It believed that happiness and salvation result just from carrying out the prescriptions of the Veda, not from the practice of yoga or insight into the One. It criticized particularly sharply other scriptural traditions (Buddhism and Jainism) that claimed to have originated from omniscient preceptors.

MIMĒSIS

A crucial term in the literary theories of Plato and Aristotle, *mimēsis* describes the relation between the words of a literary work and the actions and events they recount. In Plato, the term usually means 'imitation' and suggests that poetry is derived from and inferior to reality; in Aristotle, it loses this pejorative connotation and tends to mean simply 'representation' and to indicate that the world presented in a poem is much like, but not identical with, our own.

MIND, BUNDLE THEORY OF

This theory owes its name to Hume, who described the self or person (which he assumed to be the mind) as 'nothing but a bundle or collection of different perceptions, which succeed each other with an inconceivable rapidity, and are in a perpetual flux and movement' (*A Treatise of Human Nature* I, IV, §VI). The theory begins by denying Descartes' *Second Meditation* view that experiences belong to an immaterial soul; its distinguishing feature is its attempt to account for the unity of a single mind by employing only relations among the experiences themselves rather than their attribution to an independently persisting subject. The usual objection to the bundle theory is that no relations adequate to the task can be found. But empirical work suggests that the task itself may be illusory.

Many bundle theorists follow Hume in taking their topic to be personal identity. But the theory can be disentangled from this additional burden.

MIND, COMPUTATIONAL THEORIES OF

The computational theory of mind (CTM) is the theory that the mind can be understood as a computer or, roughly, as the 'software program' of the brain. It is the most influential form of 'functionalism', according to which what distinguishes a mind is not what it is made of, nor a person's behavioural dispositions, but the way in which the brain is organized. CTM underlies some of the most important research in current cognitive science, for example, theories of artificial intelligence, perception, decision making and linguistics.

CTM involves a number of important ideas. (1) Computations can be defined over syntactically specifiable symbols (that is, symbols specified by rules governing their combination) possessing semantic properties (or 'meaning'). For example, addition can be captured by rules defined over decimal numerals (symbols) that *name* the numbers. (2) Computations can be analysed into 'algorithms', or simple step-by-step procedures, each of which could be carried out by a machine. (3) Computation can be generalized to include not only arithmetic, but deductive logic and other forms of reasoning, including induction, abduction and decision making. (4) Computations capture relatively autonomous levels of ordinary psychological explanation different from neurophysiology and descriptions of behaviour.

MIND, IDENTITY THEORY OF

Introduction

We know that the brain is intimately connected with mental activity. Indeed, doctors now define death in terms of the cessation of the relevant brain activity. The identity theory of mind holds that the intimate connection is identity: the mind is the brain, or, more precisely, mental states are states of the brain. The theory goes directly against a long tradition according to which mental and material belong to quite distinct ontological categories – the mental being essentially conscious, the material essentially unconscious. This tradition has been bedevilled by the problem of how essentially immaterial states could be caused by the material world, as would happen when we see a tree, and how they could cause material states, as would happen when we decide to make an omelette.

A great merit of the identity theory is that it avoids this problem: interaction between mental and material becomes simply interaction between one subset of material states, namely certain states of a sophisticated central nervous system, and other material states. The theory also brings the mind within the scope of modern science. More and more phenomena are turning out to be explicable in the physical terms of modern science: phenomena once explained in terms of spells, possession by devils, Thor's thunderbolts, and so on, are now explained in more mundane, physical terms. If the identity theory is right, the same goes for the mind. Neuroscience will in time reveal the secrets of the mind in the same general way that the theory of electricity reveals the secrets of lightning. This possibility has received enormous support from advances in computing. We now have at least the glimmerings of an idea of how a purely material or physical system could do some of the things minds can do.

Nevertheless, there are many questions to be asked of the identity theory. How could states that *seem* so different turn out to be one and the same? Would neurophysiologists actually see my thoughts and feelings if they looked at my brain? When we report on our mental states what are we reporting on – our brains?

1 Origin of the identity theory

The identity theory of mind holds that each and every mental state is identical with some state in the brain. My desire for coffee, my feeling happy, and my believing that the dog is about to bite are all states of my brain. The view is not that mental states and brain states are correlated but that they are literally one and the same. Despite its name, the identity theory of mind is strictly speaking not a view about the mind as such, but about mental phenomena. However, most protagonists of the identity theory, and most contemporary philosophers of mind if it comes to that, hold some version

of the view that the mind is a construction out of its states in somewhat the way that an army is a construction out of its soldiers.

The identity theory of mind arose out of dissatisfaction with dualism, and with behaviourism as an attempt to avoid dualism. According to dualism, mental states are quite distinct from any material states, including brain states (see DUALISM). The most famous challenge to dualism is to give a satisfactory account of the causal interactions between mental states and material states, and most especially to give a satisfactory account of causation from mental states to bodily occurrences. We believe that sometimes my desire for ice cream causes my arm to move in such a way that an ice cream is in my mouth, that my pangs of hunger cause me to tighten my belt, and so on. But how do states allegedly 'outside' the material world cause material goings on like arm movements? How do they do this in such a way as to avoid violating the various conservation laws in physics? And how do they do this in such a way as not to conflict with what the physical sciences, and especially neuroscience, tell us about how bodily movements are caused?

The last question is particularly pressing. The success of the physical sciences in explaining phenomena in their own, physical, terms has been striking. We now know that lightning is not caused by Thor's actions, that epilepsy is not caused by demonic possession, and that plants do not grow because they contain a vital essence but because their cells divide (see VITALISM). It is hard to believe that bodily behaviour is unique in resisting in-principle explanation in purely physical terms. The dualist can respond to this challenge by denying the common-sense view that mental states sometimes cause bodily behaviour, a position known as epiphenomenalism. This position holds that although physical states on occasion cause mental states, mental states themselves never cause anything, being mere epiphenomena of the brain states that, along with the appropriate material surroundings, are the true causes of the behaviour we associate with mental states. Apart from flying in the face of common sense, this position makes it hard to see why the mind evolved (see EPIPHENOMENALISM).

Behaviourism treats mental states in terms of behaviour and dispositions to behaviour. Its inspiration comes from facts such as these: that those creatures we credit with mental states are precisely those manifesting sophisticated behaviour and possessing sophisticated behavioural capacities; that psychology became a serious science when psychologists started to investigate the mind via the investigation of behavioural capacities; and that there are conceptual links between mental states and behaviour – it is, for instance, part of the concept of an intention that having an intention goes along with behaving in a way that tends to fulfil it, and it is part of the concept of intelligence that the intelligent are better problem solvers than the unintelligent (see BEHAVIOURISM, ANALYTIC).

Behaviourists delight in pointing out that it is hard to see how dualists could explain the last two points. Why should investigation of an immaterial realm be especially aided by looking at behaviour? How could the way things are in some immaterial realm be *conceptually* linked to brute behavioural facts? However, for our purposes here the crucial point is that behaviourists, like dualists, have trouble over the causation of behaviour.

The common-sense position is that mental states are causally responsible for behaviour – the itch causes the scratching – and responsible for behavioural dispositions and capacities – people's intelligence is responsible for their capacity to solve hard problems. But then mental states are not the same as behaviour and behavioural dispositions and capacities, being rather their underlying causes. And so they are, says the identity theorist. Mental states are those brain states that all the scientific evidence points to as being causally responsible for the behaviour, and behavioural dispositions and capacities, distinctive of those creatures we credit with a mental life.

2 Early objections

Here are some of the many objections that greeted the identity theory when it became well known.

It was objected that the ancients knew about mental states while knowing next to nothing about the brain. How could this be if mental states are identical with brain states? However, as identity theorists observed, science has established many identities that were unknown to the ancients. They did not know that lightning is identical with an electrical discharge, temperature in gases is mean molecular kinetic energy, and water is H_2O. The identity of mental states with brain states is, identity theorists urged, of a piece with scientific identities in general. We learned, for example, that temperature is mean molecular kinetic energy by discovering that it is mean molecular kinetic energy that is responsible for the phenomena we associate with temperature. In the same general way, identity theorists claim, we have discovered that mental states are brain states by discovering that brain states are responsible for the behavioural phenomena that we associate with mental states, and we will discover which particular brain states are which particular mental states by discovering which particular brain states are responsible for the behavioural phenomena associated with those mental states.

Identity theorists also noted that water, lightning and temperature do not present themselves to us *as* H_2O, electrical discharge and mean molecular kinetic energy, respectively; so it cannot be an objection to their theory that mental states do not present themselves *as* brain states.

Many objected that the identity theory violates Leibniz's Law that if $x = y$, then x and y share all properties (see IDENTITY), on the ground that mental states and brain states differ in their properties. An after-image is, say, yellow and in front of my face, but my brain states are not yellow, and are inside my head; again, an itch is, say, in the middle of my back, but my brain is not in the middle of my back. They also pointed out that brain states are at a certain temperature but that it is surely absurd to hold that my belief that the Earth is not flat is at a certain temperature.

Identity theorists replied by arguing that our talk about mental states is, from a logical point of view, misleading. We talk as if mental states involved relations to mental objects. We say, for example, 'I have a headache', and this apparently has the same logical structure as 'I have a car': in both cases we seem to be asserting a relation between a person, me, and an object – a headache in one case, a car in the other. However, as identity theorists noted, cars are very different from headaches: cars can exist without their owners (if I die suddenly, my car will go on existing), but headaches cannot exist independently of being experienced (if I die, any headache of mine necessarily dies with me). Headaches, and mental states in general, are necessarily someone's. In consequence, they argued, we should think of headaches in the way we think of limps: limps are not things we have when we limp. When I say that I have a limp, I am simply saying that I limp; similarly, to say that I have a headache is to say that my head aches. Attributing properties to aches and limps is really attributing properties to ach*ings* and limp*ings*. To have a bad limp is to limp badly, and to have a winning smile is to smile winningly; likewise, to have a bad headache is to have a head that aches badly. Strictly speaking, there are no mental objects, and so, in particular, no after-images to be yellow and in front of faces, and no itches to be in backs; there are experiences of having after-images and of having one's back itching. These experiences are not yellow, not in front of us or in our backs, and so the fact that brain states are not yellow, not in front of us and not in our backs is no objection to the identity theorist's claim that these experiences are identical with brain states.

The discussion of belief followed a different course. There is an important distinction between my believing something, my state of belief, and what I believe. My believing that there is a tiger before me is, most likely, caused by seeing a tiger and is a state of mine, whereas what I believe – that there is a tiger before me, the *proposition* believed, as it is often put (see PROPOSITIONAL ATTITUDES) – is not caused by my seeing the tiger and is not a state of mine. Again, there is my belief that the Earth is not flat, thought of as a state of mine that causes me, say, to reassure a traveller that they do not have to worry about falling off the edge, and there is the proposition that the Earth is not flat, which is *what* I accept. Now, the identity theory is not a view about the objects of belief, the propositions; it restricts itself to claiming that the state of believing is a state of the brain. And, identity theorists argued, although it would be absurd to hold that the objects of belief are at a certain temperature, it is not absurd to hold that the believings are.

Finally, some philosophers objected that the behaviour associated with having a mind, and in particular, that associated with intelligence, rationality and free action, displays a flexibility and sophistication incompatible with a purely material etiology. There are complex issues here, but we can note two serious problems for this objection. First, computers have enlarged our conception of the behavioural flexibility and sophistication compatible with a purely material etiology; and, second, it is hard to see how having an *immaterial* etiology would make any difference to the conceptual issues at stake (and, of course, quantum mechanics has broken the tie between having a material etiology and being determined).

3 Qualia

There was, however, one early objection to the identity theory that proved harder to dismiss. It concerns a perennial problem in the philosophy of mind: the nature of conscious experience and the sensuous side of psychology. But first, some stage setting.

The identity theory of mind is typically seen as part of the programme of giving a purely naturalistic or physicalistic view of the mind (see MATERIALISM IN THE PHILOSOPHY OF MIND). It is not a species of dual attribute theory of mind, according to which, although mental states are brain states they are brain states with special, non-physical properties, properties quite distinct from the kinds of properties neuro-science in particular, and the physical sciences in general, might attribute to them. The problem with dual attribute theories is that the question of how, in the light of what science is teaching us about the physical nature of the causation of behaviour, these non-physical properties could be causally relevant to behaviour seems just as pressing as the question, raised earlier, of how

non-physical states could be causally relevant to behaviour. In consequence, most identity theorists see their theory as a purely naturalistic account of the mind: the denial of 'spooky' properties or attributes is as much part of the theory as the denial of 'spooky' entities or states.

The perennial objection is that the identity theory, when seen, as it should be, as part of a purely naturalistic view of the mind, leaves out the nature of conscious mental experience, the phenomenal side of psychology. We distinguish those mental states that are not associated with a characteristic 'feel' from those that are. Paradigmatic examples are belief, on the non-sensuous side, and bodily sensations and sensory perceptions, on the sensuous side. My belief that the world is round does not have a characteristic conscious feel available to introspective awareness; my itch and my sensing of a red sunset do. But, runs the objection, no amount of neurophysiological information about our brains tells us what it is like to itch, see a sunset, or smell a rose. Protagonists of this objection often use the term 'qualia' ('quale' is the singular) for the special properties that they insist that the identity theory leaves out of account. Typically, they hold that these qualia are epiphenomenal features. They avoid the implausibility of denying that pains and sensings of red *per se* are causally inefficacious but acknowledge that they have to allow that the *distinctive feel* of pains and sensings of red is causally irrelevant (see QUALIA).

4 Functionalism and the identity theory

When identity theorists first discussed the qualia objection they urged that when we itch, smell a rose, and quite generally when we are in a mental state, we are not introspectively aware of the intrinsic nature of the mental state. For they granted, as we noted earlier, that mental states do not present themselves to us as states of the brain. The identity theorists held that what happens when we introspect is that we are aware of highly relational properties of our mental states, properties like being like what goes on in me when a pin is stuck in me (in the case of pain), being like what goes on in me when I see blood and geranium petals (in the case of sensing red), and being of a kind apt for the production of scratching behaviour (in the case of itches). In bringing relational properties into the picture, the early identity theorists can be seen as precursors of functionalist theories of mind. For functionalism is a theory according to which what makes something the mental state it is is a highly relational feature of it, that feature known as its functional role.

According to functionalism, we can think of mental states as causal intermediaries between inputs from the environment, outputs in the form of behavioural responses, and other mental states. Pain, for instance, is an internal state that is typically caused by bodily damage, and typically causes the desire that it itself cease along with behavioural responses that tend to minimize the damage. The perception that there is coffee in front of me is an internal state typically caused by coffee in front of me, which in turn causes belief that there is coffee in front of me, and this belief, when combined with desire for coffee, typically causes movement towards the coffee. Mental states are, that is, specified in terms of their place in a huge network of interlocking states (of which we have just described a tiny fragment) (see FUNCTIONALISM). Our concern here is with the implications of this general approach for the identity theory.

Functionalism can be, and often is, regarded as entirely consonant with the identity theory, being indeed a good way of arguing for it; or functionalism can be, and often is, regarded as a major objection to the identity theory. It all depends on the kind of identity theory.

If mental states are defined by their place in a network, then the question of what some given mental state *is* comes down to the question of what state occupies the relevant place in the network. An analogy: money can be defined in terms of a characteristic functional role, a role we are all only too familiar with through our knowledge of what you can do if you have money, and cannot do if you do not have money. In consequence, the question of what money is is the question of what plays, or occupies, the money-functional role, be it paper notes, coins, cowrie shells, or whatever. But, identity theorists observe, by far the most plausible candidates for what play the functional roles associated with mental states are various states of the brain. Thus, functionalism gives us a simple argument for the identity theory of the following structure: pain = what plays the pain-role; what plays the pain-role = a state of the brain (say, C-fibres firing); therefore, pain = C-fibres firing. And likewise for all the mental states. Identity theorists who see the identity theory as a natural offshoot of functionalism, often refer to the identity theory as 'central state materialism'.

Approaching the identity theory through functionalism commits identity theorists to an anti-essentialist theory of mind. For the brain state that occupies the pain-role and so is, according to them, pain, might not have done so, and so might not have been pain. And the same goes for all mental states. Early expositions of the identity theory made this point by insisting that the identity of pain with, say, C-fibres firing was a *contingent* identity, and drew an analogy in this regard with the scientific identities

we mentioned before. However, at least some of these identities are arguably necessarily true. It is arguable that water is necessarily H_2O. Certainly, we had to discover the identity of water and H_2O by empirical investigation, which makes it an a posteriori matter, but what we discovered was an essential feature of water. However, the identity theory must hold that the identities it posits are contingent. They are like the identity of the President of the United States in 1997 with Bill Clinton, which is contingent because that which occupies the role definitive of being President in 1997 is a contingent matter. (Dole was swimming against an economic tide, not a logical one.)

Although functionalism is a good way of arguing for the identity theory, it is a major objection to one kind of identity theory. We noted that identity theorists appeal to scientific identities in explaining and introducing their theory. These identities concern kinds or *types*. When scientists tell us that lightning is an electrical discharge, they are not merely telling us that the instance or *token* of lightning we saw last night is an instance or token of an electrical discharge; they are telling us, in addition, about what kind of happening lightning in general is. Again, the claim that temperature is mean molecular kinetic energy is a claim about kinds or types; it tells us what the property of temperature (in gases, anyway) is – namely, mean molecular kinetic energy. This suggests that we should think of the (mind-brain) identity theory as a type-type identity theory. Moreover, the theorists' favourite illustration – 'Pain = C-fibres firing' – is a type-type identity statement.

The problem is that different types of state might occupy the pain-role in different creatures. Perhaps it is C-fibres firing in humans but D-fibres firing in dolphins. But dolphins with their D-fibres firing would then be just as much in pain as we are when our C-fibres are firing. It is the role occupied, not the occupier, that matters for being in pain according to functionalism. And the point is independently plausible. We feel sorry for dolphins that exhibit all the signs of pain despite not knowing in any detail how intrinsically alike our and their brains are. But the identity theorist cannot allow both that pain = C-fibres firing, and that pain = D-fibres firing. That would, by the transitivity of identity, lead to the false contention that C-fibres firing = D-fibres firing.

Two responses are possible. Identity theorists can retreat to a token-token identity theory. Each and every token or instance of mental state M is some token brain state, but mental types are not brain types, being instead functional types. Alternatively, they can allow that the identities between mental types and brain types may need to be restricted. Think again of the example of money. Although different types of things are money in different societies, we can make true identity claims about the types of things that are money in the different societies. For instance, money in our society = notes and coins produced by the mint, whereas money in early Polynesian society = cowrie shells (or whatever). Similarly, although temperature in gases = mean molecular kinetic energy, in substances of which the molecules do not move freely it is something else. In the same way, if indeed it is C-fibres in us but D-fibres in dolphins that play the pain-role, then identity theorists must restrict themselves to 'Pain in humans = C-fibres firing' and 'Pain in dolphins = D-fibres firing'. The question of what humans in pain and dolphins in pain have in common would remain, of course, for they would not *ex hypothesi* share the same kind of brain state. And the identity theorists' answer must be that what they would have in common would be that each has a state inside them playing the pain-role, although not the same state.

MIND, PHILOSOPHY OF

Introduction

'Philosophy of mind', and 'philosophy of psychology' are two terms for the same general area of

philosophical inquiry: the nature of mental phenomena and their connection with behaviour and, in more recent discussions, the brain.

Much work in this area reflects a revolution in psychology that began mid-century. Before then, largely in reaction to traditional claims about the mind being non-physical (see DUALISM; DESCARTES), many thought that a scientific psychology should avoid talk of 'private' mental states. Investigation of such states had seemed to be based on unreliable introspection, not subject to independent checking (see PRIVATE LANGUAGE ARGUMENT), and to invite dubious ideas of telepathy. Consequently, psychologists like B.F. Skinner and J.B. Watson, and philosophers like W.V. QUINE and Gilbert RYLE argued that scientific psychology should confine itself to studying publicly observable relations between stimuli and responses.

However, in the late 1950s, several developments began to change all this: (1) The experiments behaviourists themselves ran on animals tended to refute behaviouristic hypotheses, suggesting that the behaviour of even rats had to be understood in terms of mental states. (2) The linguist Noam CHOMSKY drew attention to the surprising complexity of the natural languages that children effortlessly learn, and proposed ways of explaining this complexity in terms of largely unconscious mental phenomena. (3) The revolutionary work of ALAN TURING (see TURING MACHINES) led to the development of the modern digital computer. This seemed to offer the prospect of creating ARTIFICIAL INTELLIGENCE, and also of providing empirically testable models of intelligent processes in both humans and animals. (4) Philosophers came to appreciate the virtues of realism, as opposed to instrumentalism, about theoretical entities in general.

1 *Functionalism and the computational theory of mind*

These developments led to the emergence in the 1970s of the loose federation of disciplines called 'cognitive science', which brought together research from, for example, psychology, linguistics, computer science, neuroscience and a number of sub-areas of philosophy, such as logic, the philosophy of language, and action theory. In philosophy of mind, these developments led to FUNCTIONALISM, according to which mental states are to be characterized in terms of relations they bear among themselves and to inputs and outputs, for example, mediating perception and action in the way that belief and desire characteristically seem to do. The traditional problem of OTHER MINDS then became an exercise in inferring from behaviour to the nature of internal causal intermediaries.

This focus on functional organization brought with it the possibility of multiple realizations: if all that is essential to mental states are the roles they play in a system, then, in principle, mental states, and so minds, could be composed of (or 'realized' by) different substances: some minds might be carbon-based like ours, some might be computer 'brains' in robots of the future, and some might be silicon-based, as in some science-fiction stories about 'Martians'. These differences might also cause the minds to be organized in different ways at different levels, an idea that has encouraged the co-existence of the many different disciplines of cognitive science, each studying the mind at often different levels of explanation.

Functionalism has played an important role in debates over the metaphysics of mind. Some see it as a way of avoiding DUALISM and arguing for a version of materialism known as the identity theory of mind (see MIND, IDENTITY THEORY OF). They argue that if mental states play distinctive functional roles, to identify mental states we simply need to find the states that play those roles, which are, almost certainly, various states of the brain. Here we must distinguish identifying mental state tokens with brain state tokens, from identifying mental types with brain types (see TYPE/TOKEN DISTINCTION). Many argue that multiple realizability shows it would be a mistake to identify any particular kind or type of mental phenomenon with a specific type of physical phenomenon (for example, depression with the depletion of norepinephrine in a certain area of the brain). For if depression is a multiply realized functional state, then it will not be identical with any particular type of physical phenomenon: different instances, or tokens, of depression might be identical with tokens of ever different types of physical phenomena (norepinephrine deletion in humans, too little silicon activation in a Martian). Indeed, a functionalist could allow (although few take this seriously) that there might be ghosts who realize the right functional organization in some special dualistic substance. However, some identity theorists insist that at least some mental state types – they often focus on states like pain and the taste of pineapple, states with QUALIA (see also the discussion later) – ought to be identified with particular brain state types, in somewhat the way that lightning is identified with electrical discharge,

or water with H_2O. They typically think of these identifications as necessary a posteriori.

An important example of a functionalist theory, one that has come to dominate much research in cognitive science, is the computational theory of mind (see MIND, COMPUTATIONAL THEORIES OF), according to which mental states are either identified with, or closely linked to, the computational states of a computer. There have been three main versions of this theory, corresponding to three main proposals about the mind's Cognitive architecture. According to the 'classical' theory, particularly associated with Jerry FODOR, the computations take place over representations that possess the kind of logical, syntactic structure captured in standard logical form: representations in a so-called LANGUAGE OF THOUGHT, encoded in our brains. A second proposal, sometimes inspired by F.P. RAMSEY's view that beliefs are maps by which we steer (see BELIEF), emphasizes the possible role in reasoning of maps and mental imagery. A third, recently much-discussed proposal is CONNECTIONISM, which denies that there are any structured representations at all: the mind/brain consists rather of a vast network of nodes whose different and variable excitation levels explain intelligent learning. This approach has aroused interest especially among those wary of positing much 'hidden' mental structure not evident in ordinary behaviour (see Ludwig WITTGENSTEIN §3 and Daniel DENNETT).

The areas that lend themselves most naturally to a computational theory are those associated with logic, common sense and practical reasoning, and natural language syntax (see RATIONALITY, PRACTICAL; SYNTAX); and research on these topics in psychology and ARTIFICIAL INTELLIGENCE has become deeply intertwined with philosophy (see SEMANTICS; LANGUAGE, PHILOSOPHY OF).

A particularly fruitful application of computational theories has been to VISION. Early work in GESTALT PSYCHOLOGY uncovered a number of striking perceptual illusions that demonstrated ways in which the mind structures perceptual experience, and the pioneering work of the psychologist, David Marr, suggested that we might capture these structuring effects computationally. The idea that perception was highly cognitive, along with the functionalist picture that specifies a mental state by its place in a network, led many to holistic conceptions of mind and meaning, according to which parts of a person's thought and experience cannot be understood apart from the person's entire cognitive system (see HOLISM: MENTAL AND SEMANTIC; SEMANTICS, CONCEPTUAL ROLE).

However, this view has been challenged recently by work of Jerry FODOR. He has argued that perceptual systems are 'modules', whose processing is 'informationally encapsulated' and hence isolatable from the effects of the states of the central cognitive system (see MODULARITY OF MIND). He has also proposed accounts of meaning that treat it as a local (or 'atomistic') property to be understood in terms of certain kinds of causal dependence between states of the brain and the world. Others have argued further that perception, although contentful, is also importantly non-conceptual, as when one sees a square shape as a diamond but is unable to say wherein the essential difference between a square and a diamond shape consists (see CONTENT, NON-CONCEPTUAL; PERCEPTION).

2 Mind and meaning

As these last issues indicate, any theory of the mind must face the hard topic of meaning (see SEMANTICS). In the philosophies of mind and psychology, the issue is not primarily the meanings of expressions in natural language, but of how a state of the mind or brain can have meaning or content: what is it to believe, for example, that snow is white or hope that you will win. These latter states are examples of propositional attitudes: attitudes towards propositions such as that snow is white, or that you will win, that form the 'content' of the state of belief or hope. They raise the general issue of intentionality, or how a mental state can be about things (for example, snow) and properties (for example, white), and, particularly, 'about' things that do not exist or will not happen, as when someone believes in Santa Claus or hopes in vain for victory.

There have been three main proposals about mental content. A state might possess a specific content: (1) by virtue of the role it plays in reasoning (see SEMANTICS: CONCEPTUAL ROLE); (2) by virtue of certain causal and lawful relations the state bears to phenomena in the world (see FUNCTIONALISM); or (3) by virtue of the function it plays in the evolution and biology of the organism (see FUNCTIONAL EXPLANATION). Related to these proposals are traditional philosophical interests in CONCEPTS, although this latter topic raises complicating metaphysical concerns with UNIVERSALS, and epistemological concerns with A PRIORI knowledge.

Special problems are raised by indexical content, or the content of thoughts involving concepts expressed by, for example, 'I myself', 'here', 'now', 'this', and 'that' (see DEMONSTRATIVES AND INDEXICALS; PROPOSITIONAL ATTITUDES). Does the thought that it is hot here, had in Maryland, have the same content as the thought that it is hot here, had in Canberra? The conditions under which such thoughts are true obviously depends upon the

external context – for example, the time and place – of the thinking.

This dependence on external context is thought by many to be a pervasive feature of content. Drawing on recent work on reference (see REFERENCE; PROPER NAMES), Hilary PUTNAM and Tyler Burge have argued that what people think, believe and so on depends not only on how they are, but also upon features of their physical and social environment. This raises the important question of whether an organism's psychology can be understood in isolation from the external world it inhabits. Defenders of methodological individualism insist that it can be (see METHODOLOGICAL INDIVIDUALISM); Putnam, Burge and their supporters that it can't. Some theorists respond to the debate by distinguishing between wide and narrow content: narrow content is what 'from the skin in' identical individuals would share across different environments, whereas wide content might vary from one environment to the next (see CONTENT: WIDE AND NARROW). These theorists then give distinctive roles to the two notions in theoretical psychology, although this is a matter of great controversy.

3 Alternatives to functionalism

Not everyone endorses functional and computational theories of mind. Some, influenced by RYLE and the later WITTGENSTEIN, think that such concern with literally inner processes of the brain betrays a fundamental misunderstanding of mental talk, which, they argue, rests largely on outward CRITERIA. Others think that computational processes lack the means of capturing the basic properties of CONSCIOUSNESS and INTENTIONALITY that are essential to most mental phenomena. JOHN SEARLE, in particular, regards his CHINESE ROOM ARGUMENT as a devastating objection to computational approaches. He thinks that mental phenomena should be understood not functionally, but directly in biological or physical terms.

The hardest challenge for functionalism is posed by QUALIA – the properties that distinguish pain, the look of red, the taste of pineapple, and so on, on the one hand, from mental states like belief and understanding on the other. (See also SENSE-DATA; PERCEPTION). Some argue that unnecessary problems are produced in this area by an excessive reification of inner experience, and recommend instead an adverbial theory of mental states. However, some problems persist, and can be made vivid by considering the possibility of 'inverted qualia'. It seems that two people might have colour experiences that are the complements of one another (red for green, yellow for blue, etc.), even though their behaviour and functional organization are identical. This issue is explored in COLOUR AND QUALIA and leads inevitably to the hard problems of CONSCIOUSNESS: What is it? What things have it? How do we tell? What causal role, if any, does it play the world?

There is also an issue for functionalists over MENTAL CAUSATION. A principal reason why DUALISM has few adherents today is the problem of explaining how non-physical or non-natural phenomena can causally affect a physical world. And although some dualists retreat to EPIPHENOMENALISM, the view that mental phenomena are caused by but do not themselves cause any physical phenomena, this is widely seen as implausible. However, functionalists also have a problem. Even though they can and do insist that functional states are realized physically, arguably the functional states *per se* do no causing; what does the causing would seem to be the underlying physical properties of the physical realization. So, although functionalists avoid giving causal roles to the 'non-natural', it seems they must allow that mental properties *per se* do no causing.

Although the view that the mind is a natural phenomenon is now widely accepted (principally because of the causal problem for dualism), what this implies is highly contentious. Some hold that it simply means that mental phenomena supervene on physical nature in the sense that there can be no mental difference without a physical difference. Donald DAVIDSON thinks this can be true without there being any strict laws connecting the physical and the mental (see ANOMALOUS MONISM). Others insist that a naturalist about the mind must reduce the mental to the physical in somewhat the way thermodynamics has been reduced to statistical mechanics, so delivering neat lawful biconditionals linking the mental and the physical (see REDUCTIONISM IN THE PHILOSOPHY OF MIND).

Much in this discussion turns on the status of FOLK PSYCHOLOGY, the theory of mind allegedly implicit in ordinary (folk) thought and talk about the mind. On one view, mental states are simply the states that fill the roles of this implicit theory, and the reduction consists in finding which internal physical states fill the roles and are, thereby, to be identified with the relevant mental states. However, defenders of ELIMINATIVISM, noting that any theory – especially a folk one – can turn out false, argue that we should take seriously the possibility that the mental states postulated by folk psychology do not exist, much as it turned out that there are no witches or phlogiston.

4 Issues in empirical psychology

Empirical psychology has figured in philosophy not only because its foundations have been discussed in

the above ways, but also because some of its specific findings have been relevant to traditional philosophical claims. Thus, experiments on split brains have undermined traditional conceptions of personal identity (see also MIND, BUNDLE THEORY OF), and research on the reliability of people's self-attribution of psychological states has cast doubts on introspection as a source of specially privileged knowledge about the mind. The work of FREUD on psychopathology (see PSYCHOANALYSIS, POST-FREUDIAN; PSYCHOANALYSIS, METHODOLOGICAL ISSUES IN) and of CHOMSKY in linguistics, suggests that the states of most explanatory interest are not introspectively accessible (see KNOWLEDGE, TACIT; UNCONSCIOUS MENTAL STATES). Chomsky's ideas also seem to revive RATIONALISM's postulation of innate knowledge that was long thought to have been discredited by EMPIRICISM. And they have stimulated research beyond knowledge of grammar, into infant cognition generally (some of which treats the Molyneux problem of whether newly sighted people would be able to recognize shapes that they had previously only touched). Other questions about the basic categories in which people understand the world have benefited from work on how these categories are understood and evolve in childhood (see PIAGET, J.; MOLYNEUX PROBLEM). A particularly important issue for the philosophy of mind concerns the origin of our mental concepts, a topic of lively current research that affects our understanding of folk psychology.

5 Philosophy of action

Whether or not it is ultimately vindicated by empirical research, folk psychology is a rich fund of distinctions that are important in human life. The examination of them has tended to focus on issues in the explanation of ACTION, and, in a related vein, on psychological issues relevant to ethics (see MORAL PSYCHOLOGY).

The traditional view of action, most famously advocated by David HUME, is that an action needs both a desire and a belief. The desire provides the goal, and the belief the means of putatively achieving it (see also REASONS AND CAUSES; DESIRE; BELIEF). But what then is the role, if any, of INTENTION? Are intentions nothing more than some complex of belief and desire? And how, if at all, do we find a place in the Humean picture for the will? Is it something that can somehow act independently of beliefs and desires, or is it some kind of manifestation of them, some kind of 'all things considered' judgment that takes a person from dithering to action? (See WILL, THE.) Notoriously difficult questions in this regard concern whether there actually is anything as FREE WILL, and how it is possible for a person to act against their better judgement, as they seem to do in cases of AKRASIA, or 'weakness of will'.

Beliefs and desires seem intimately connected with many other mental states. Belief about the past is of the essence of memory. Perception delivers belief about how things are around one, and dreaming seems to be the having of experiences during sleep akin to (rather fragmented) perceptions in the way they tend to make you believe that certain things are happening. Even emotions and bodily sensations seem to have belief and desire components (see EMOTIONS, NATURE OF): anger involves both a belief that one has been wronged and a desire to do something about it, and pain involves the belief that something is amiss and the desire that it stop. Much contemporary philosophy of mind and action is concerned with teasing out the relationship between beliefs and desires and various other mental states, although approaches in cognitive science often focus upon more computationally active states, such as: noticing, deciding, and 'on line' processes of reasoning.

MIRACLES

Introduction

Does God at times miraculously intervene in earthly affairs? That is, do some events occur because God has entered our space-time continuum and directly

modified or circumvented the relevant natural laws? Few philosophers today deny that this is possible. But many question whether we could ever justifiably maintain that such intervention has taken place.

According to some philosophers, it is not even necessary to grant that the types of events believers label miracles – for instance, healings or resurrections – actually occur as reported. Since the evidence supporting the occurrence of such events is the personal testimony of a few, possibly biased, individuals, while the basis for doubt is the massive amount of objective research upon which the relevant laws are based, it is always justifiable, according to this view, to conclude that such reports are erroneous. Others contend, however, that the presence of some forms of evidence – for instance, independent confirmation from reputable sources – could make it most reasonable in some cases to acknowledge that even the most unexpected of events had actually occurred.

Some philosophers also deny that we could ever justifiably conclude that an event could not have been produced by natural causes alone. Since we will never be in a position to identify all that nature can produce, they declare, it will always be most reasonable for the scientist facing a currently unexplainable counterinstance to a natural law to continue to look for a natural explanation. Many believers, however, are quite willing to grant that nature could in principle produce any event, since what they wish to maintain is only that nature does not do so in the case of miraculous interventions.

Finally, while many philosophers acknowledge that belief in direct divine intervention may at times be justifiable for those who already believe that God exists, some also argue that no single event or series of events could ever compel all thoughtful individuals to acknowledge the existence of a perfectly good supernatural causal agent, given all we experience – for instance, the tremendous amount of horrific evil in our world. Many believers, though, are also willing to grant this point.

1 Definition

The term 'miracle' is sometimes used in ordinary discussions to refer to the occurrence of any unexpected event – from the sudden discovery of a lost possession to the unanticipated passing of an exam. Within philosophical circles, however, 'miracle' is almost always discussed in its more restricted sense: as a designation for an unusual event that is the result of direct divine circumvention or modification of the natural order.

Philosophers, as well as religious believers, differ on the exact nature of the conceptual relationship between miraculous divine interventions and the natural order. For those who understand miracles to be violations of natural laws, a miracle is not simply an event that nature *did* not alone produce. It is an event that nature *could* not have produced on its own – an event that will always be incompatible with the relevant natural laws (see LAWS, NATURAL). For example, as proponents of the violation model understand it, to maintain that someone has miraculously been healed, it is not sufficient to maintain simply that God was directly involved. It is also necessary to maintain that the state of affairs in question could not have occurred naturally (that no totally natural explanation could be forthcoming).

Other philosophers, and many believers, however, deny that a miraculous divine intervention must be defined as an event for which no plausible natural explanation is, or could be, available. It is sufficient, they believe, to maintain that God was directly involved. For example, to maintain that someone's cancer has miraculously entered remission, it is not necessary to hold that nature alone could not have brought it about (to maintain that it could not have happened naturally). It is sufficient to maintain that nature alone did not do so in this case.

2 The possibility of miracles

Some philosophers have claimed that the concept of a miracle, if defined as a violation of a natural law, is incoherent. Natural laws, they point out, are really only generalized descriptions of what does in fact happen. That is, these laws summarize for us the actual course of events. Accordingly, to claim that an occurrence is a violation of a natural law is to claim that the event in question is a suspension of the actual course of events and this is, of course, impossible. Events may well occur, they acknowledge, that seem at present to be incompatible with how we believe things normally happen. But a true counterinstance to what we now believe to be a natural law only shows the law to be inadequate. Since natural laws, by definition, only summarize what actually occurs, we must always be willing in principle to expand our laws to accommodate any occurrence, no matter how unusual. We can never have both the exception and the rule.

Others, however, take this line of reasoning to be based on a confusion. To maintain that a natural law

accurately describes the natural order, they point out, is to say only that it correctly identifies that which will occur under a specific set of natural conditions. But to maintain that an event is a miraculous counterinstance to a natural law is not to maintain that some event has occurred under the exact set of natural conditions covered by this law and nothing more. To say that water has miraculously turned into wine, for example, is not to say that water has turned into wine only under the exact set of natural conditions under which the relevant laws tell us this will not occur. It is to maintain that an additional non-natural causal factor, namely direct divine activity, was also present in this case. Accordingly, these philosophers contend, unless it is assumed that supernatural activity is impossible, it cannot be assumed that a miraculous counterinstance to a natural law – a counterinstance produced in part by divine circumvention or modification of the natural order – is conceptually impossible. That is, unless it is assumed that supernatural intervention is impossible, we can have both the exception and the rule.

Of course, many individuals do in fact deny the existence of any type of supernatural being. And even some who affirm the existence of such a being – for example, process theists (see PROCESS THEISM) – deny that this being can unilaterally intervene in earthly affairs in the sense necessary to produce miraculous events. However, few philosophers today maintain that the existence of a supernatural being, or the ability of such a being (if it exists) to intervene, can be demonstrated to be impossible. That is, while most philosophers agree that the existence of a supernatural being who intervenes in earthly affairs can justifiably be denied, most also agree that it is possible to maintain justifiably that such a being does exist. Consequently, few deny that miracles, even if defined as violations of natural laws, could occur. Since the time of David HUME (§6), however, philosophers have continued to debate vigorously a number of questions related to our ability to *identify* miraculous events.

3 The credibility of personal testimony

One such question is whether we need even acknowledge that alleged counterinstances to well-confirmed natural laws actually occur. Most philosophers agree that reports of repeatable counterinstances – counterinstances that can in principle be produced by anyone under a specified set of natural conditions – cannot justifiably be dismissed. But there are a number of philosophers who believe that if the events in question are nonrepeatable – if they cannot be reproduced under specifiable natural conditions – the situation is quite different. It is clearly possible, they acknowledge, that nonrepeatable counterinstances to well-confirmed natural laws have occurred (or will occur). They acknowledge, for instance, that nonrepeatable counterinstances to our current laws describing the properties of water or human tissue may have occurred (or might occur). However, the evidence supporting the adequacy of laws of this type, they point out, is very strong. These laws not only can be, but are, tested and reconfirmed daily by people with no vested interest in the outcome.

On the other hand, they are quick to add, reports of presently nonrepeatable counterinstances to such laws – a claim, for instance, that water has turned into wine or that someone has been raised from the dead – will be supported at best only by the personal testimony of a few people who may well have a vested interest in the outcome. Consequently, as long as alleged counterinstances remain nonrepeatable, we can never possess better reasons for believing that the events in question have actually occurred as reported than for believing that they have not. And therefore, following the Humean maxim that the wise person proportions belief to the evidence, these philosophers conclude that it is always justifiable to deny the accuracy of such reports.

However, there are those (for instance, Swinburne) who believe that this conclusion is much too strong. They acknowledge that reports of seemingly nonrepeatable counterinstances to well-established laws must be approached with appropriate scepticism, since deception or misperception is always possible. But from their perspective it is unreasonable to assume that the evidence supporting even the most highly confirmed laws would *always* furnish a sufficient basis for dismissing reports of counterinstances to them.

First and foremost, they argue that to make this assumption fails to take into account the *prima facie* reliability of our visual belief-forming faculties. We all rely on these faculties daily and, in general, they serve us quite well. In fact, the general reliability of such faculties must be presupposed by those formulating our natural laws. Thus, in cases where we had no reason to doubt the reliability of these belief-forming faculties – for instance, if we were to observe a seeming counterinstance ourselves or if it were directly observed by a friend whose character and objectivity were beyond question – it is not clear, they maintain, that it would always be justifiable to decide in favour of the natural laws in question, even if they were very well established.

Moreover, these philosophers add, we might in some cases have compelling physical traces to consider. In the case of an alleged healing that

runs counter to well-established laws, for instance, we might have more than personal testimony. We might have objective data – photographs or videotapes or X-rays or medical records – that would stand as strong evidence for the occurrence of the event in question, evidence so convincing that it would be unreasonable to reject it. Thus they conclude that decisions concerning the accuracy of reports of alleged counterinstances – even if the events in question are nonrepeatable – must be made on a case-by-case basis.

4 Miracles as events unexplainable by natural causes

Even if some occurrences can justifiably be labelled counterinstances to our current laws, could we ever be in a position to maintain justifiably that any such event is permanently unexplainable scientifically? That is, could we ever be in a position to maintain that an acknowledged counterinstance is a state of affairs that nature could never produce on its own?

In addressing this question, it is important to clarify a potential ambiguity that has been glossed over so far in this entry. By definition, no specific state of affairs produced even in part by direct supernatural activity (by direct circumvention or modification of the natural cause/effect patterns) could ever be given a totally natural explanation. Accordingly, if we were ever in a position to maintain justifiably that some event was actually a direct act of God, we would automatically be in a position to maintain justifiably that this specific occurrence was, itself, permanently unexplainable scientifically.

As currently understood by most philosophers, however, the primary purpose of natural science is not to determine what nature has in fact produced. The main objective of science, rather, is to determine what nature is capable of producing – what can occur under solely natural conditions. For instance, the primary purpose of natural science is not to determine whether natural factors alone actually did cause any specific person's cancer to enter remission. The primary purpose of science is to determine whether natural factors alone could have done so.

Hence, when philosophers ask whether we could ever be in a position to maintain justifiably that an event is permanently unexplainable scientifically, they are not asking whether we could ever be in a position to maintain justifiably that a specific state of affairs *was* not produced by nature alone. They are asking, rather, whether we could ever be in a position to maintain justifiably that a specific event *could* not have been produced by nature alone.

In considering this question, it should first be noted that no philosopher believes that we as human beings are in a position to state with absolute certainty what nature could or could not produce on its own. All acknowledge that the scientific enterprise is continually discovering new, often startling and unexpected, information about the causal relationships that obtain in our universe. And all freely admit that the annals of science record numerous instances in which supposed counterinstances to natural laws were later demonstrated to be consistent with such laws or revisions of them.

However, as some philosophers (such as Swinburne) see it, some of our natural laws are so highly confirmed that any modification we might suggest to accommodate counterinstances would be clumsy and so *ad hoc* that it would upset the whole structure of science. For example, from their perspective, to attempt to modify our current laws relating to the properties of water to allow for the possibility that water could turn into wine naturally, or to attempt to modify our current laws relating to the properties of nonliving human tissue to allow for the possibility that a dead body could be resuscitated naturally, would make these laws of little practical value. Consequently, if we were in a position to maintain justifiably that a counterinstance to a law of this type had actually occurred, we would be required, for the sake of the scientific enterprise, to maintain that this event was permanently unexplainable by natural causes – that this event could never have been produced by nature on its own.

Critics consider this line of reasoning to contain a false dilemma. If faced with an acknowledged counterinstance to a natural law, even one that was very highly confirmed, we would not, they contend, be required at that moment either to modify the law to accommodate the occurrence or to affirm the adequacy of the law and declare the event permanently unexplainable by natural causes. Rather, since only naturally repeatable counterinstances falsify natural laws, the appropriate initial response to the occurrence of any seeming counterinstance to any law, no matter how highly confirmed, would be to acknowledge both the law and the counterinstance while further research was undertaken.

Moreover, these critics argue that such research could never make it most reasonable to conclude that something beyond the ability of nature to produce had actually occurred. If it were discovered that the seeming counterinstance was naturally repeatable – if it were found that the event in question could be produced with regularity under some set of purely natural conditions – a revision of the relevant laws would indeed be necessary. But then this event would no longer be naturally unexplainable. On the other hand, if natural repeatability could not be achieved, the appropriate

response, they contend, would still not be to maintain that this occurrence was permanently unexplainable. Since nonrepeatable counterinstances do not present us with competing hypotheses to the relevant law(s), the appropriate response, rather, would be to label the counterinstance an anomaly while continuing to accept the functional adequacy of the law(s) in question.

Even if this line of reasoning is correct, however, nothing of significance follows for those who maintain only that a miracle is an event that would not have occurred at the exact time and in the exact manner it did if God had not somehow directly circumvented or modified the natural order in the specific case in question. Only those who believe that a miracle must be a violation of a natural law – who believe that a miracle must be an event that nature could not have produced – are affected.

5 Miracles as acts of God

Regardless of the perceived relationship between miracles and nature, however, questions concerning our ability (or inability) to identify events as direct acts of God remain important. For many philosophers, the most significant question of this sort continues to be whether there are imaginable conditions under which all rational individuals would be forced to acknowledge that God has directly intervened. And although most philosophers believe the answer to be no, some (for example, Larmer) believe an affirmative response is required. They acknowledge that with respect to many states of affairs which believers do in fact maintain have been brought about by God – for example, many alleged cases of divine healings – it is possible for a rational person to grant that the event has occurred as reported and yet justifiably deny that it was the result of direct divine intervention. But let us assume that someone who has been dead for twenty-four hours is raised from the dead when divine intervention is requested. Or let us assume that the missing fingers of a leper instantaneously reappear following a prayer for healing. In such cases, they argue, there would be very strong evidence supporting supernatural causation and no evidence supporting purely natural causation. In fact, the evidence would be so strong that to continue to hold out indefinitely for a totally natural explanation in such contexts would be unjustified in that this would simply demonstrate an unreasonable a priori naturalistic bias.

In response, critics do not deny that there might be conceivable cases which, if considered in isolation, would appear to make divine intervention a very plausible causal hypothesis. However, to acknowledge that God exists and has beneficially intervened in some specific case(s), they point out, is also to acknowledge that God's existence is compatible with all we experience – for example, that it is compatible with the tremendous amount of horrific human pain and suffering that appears to fall disproportionately on the innocent and disadvantaged. And even if it is possible to claim justifiably that God's existence is compatible with all we experience, it cannot be argued successfully that everyone must agree. Disbelief in God also remains a justifiable response (see EVIL, PROBLEM OF §6). Consequently, these critics conclude, the belief that there exists a solely natural cause for any specific occurrence always remains a justifiable option, regardless of the extent to which it may appear that divine intervention was involved.

For many philosophers, though, the crucial question is not whether there are imaginable conditions under which all rational individuals would be compelled to acknowledge divine intervention but rather whether there are conditions under which those who already believe in God would be justified in doing so. Even if it is true that the occurrence of no single event (or set of events) can justifiably compel belief in divine intervention, it is also true (so some philosophers contend) that the occurrence of no event (or set of events) – for instance, no amount of evil – can rule out justified belief in God's existence as a supernatural causal agent in our world. And given this fact, it is argued, as long as believers themselves possess good theistic reasons for assuming that God has directly intervened in a given case – for instance, because the occurrence appears clearly to fit an accepted pattern of divine action – they are justified in making this assumption.

It must be added, however, that even if this is correct, an important inverse relationship between miracles and evil remains. For instance, to respond to evil by claiming that God cannot both grant humans significant freedom and yet beneficially intervene on a consistent basis is, at the same time, to cite a reason why miracles should not be expected with frequency. And to respond to evil by claiming that 'God's ways are above our ways' places the believer in a less secure position to say when and where miraculous intervention has occurred.

MODAL LOGIC

Modal logic, narrowly conceived, is the study of principles of reasoning involving necessity and possibility. More broadly, it encompasses a number of structurally similar inferential systems. In this sense, deontic logic (which concerns obligation, permission and related notions) and epistemic logic (which concerns knowledge and related notions) are branches of modal logic. Still more broadly, modal logic is the study of the class of all possible formal systems of this nature.

It is customary to take the language of modal logic to be that obtained by adding one-place operators '□' for necessity and '◇' for possibility to the language of classical propositional or predicate logic. Necessity and possibility are interdefinable in the presence of negation:

$$\Box A \leftrightarrow \neg\Diamond\neg A \text{ and}$$
$$\Diamond A \leftrightarrow \neg\Box\neg A$$

hold. A modal logic is a set of formulas of this language that contains these biconditionals and meets three additional conditions: it contains all instances of theorems of classical logic; it is closed under *modus ponens* (that is, if it contains A and $A \rightarrow B$ it also contains B); and it is closed under substitution (that is, if it contains A then it contains any substitution instance of A; any result of uniformly substituting formulas for sentence letters in A). To obtain a logic that adequately characterizes metaphysical necessity and possibility requires certain additional axiom and rule schemas:

$$\begin{array}{rl} K & \Box(A \rightarrow B) \rightarrow (\Box A \rightarrow \Box B) \\ T & \Box A \rightarrow A \\ 5 & \Diamond A \rightarrow \Box\Diamond A \\ \textit{Necessitation} & A/\Box A. \end{array}$$

By adding these and one of the □–◇ biconditionals to a standard axiomatization of classical propositional logic one obtains an axiomatization of the most important modal logic, S5, so named because it is the logic generated by the fifth of the systems in Lewis and Langford's *Symbolic Logic* (1932). S5 can be characterized more directly by possible-worlds models. Each such model specifies a set of possible worlds and assigns truth-values to atomic sentences relative to these worlds. Truth-values of classical compounds at a world w depend in the usual way on truth-values of their components. $\Box A$ is true at w if A is true at all worlds of the model; $\Diamond A$, if A is true at some world of the model. S5 comprises the formulas true at all worlds in all such models. Many modal logics weaker than S5 can be characterized by models which specify, besides a set of possible worlds, a relation of 'accessibility' or relative possibility on this set. $\Box A$ is true at a world w if A is true at all worlds accessible from w, that is, at all worlds that would be possible if w were actual. Of the schemas listed above, only K is true in all these models, but each of the others is true when accessibility meets an appropriate constraint.

The addition of modal operators to predicate logic poses additional conceptual and mathematical difficulties. On one conception a model for quantified modal logic specifies, besides a set of worlds, the set D_w of individuals that exist in w, for each world w. For example, $\exists x\Box A$ is true at w if there is some element of D_w that satisfies A in every possible world. If A is satisfied only by existent individuals in any given world $\exists x\Box A$ thus implies that there are necessary individuals; individuals that exist in every accessible possible world. If A is satisfied by non-existents there can be models and assignments that satisfy A, but not $\exists xA$. Consequently, on this conception modal predicate logic is not an extension of its classical counterpart.

The modern development of modal logic has been criticized on several grounds, and some philosophers have expressed scepticism about the intelligibility of the notion of necessity that it is supposed to describe.

MODELS

Of the many kinds of things that serve as 'models', all function fundamentally as representations of what we wish to understand or to be or to do. Model aeroplanes and other scale models share selected structural properties with their originals, while differing in other properties, such as construction materials and size. Analogue models, which resemble their originals in some aspect of

structure or internal relations, are important in the sciences, because they can facilitate inferences about complicated or obscure natural systems. A collection of billiard balls in random motion is an analogue model of an ideal gas; the interactions and motions of the billiard balls are taken to represent – to be analogous to – the interactions and motions of molecules in the gas.

In mathematical logic, a model is a structure – an arrangement of objects – which represents a theory expressed as a set of sentences. The various terms of the sentences of the theory are mapped onto objects and their relations in the structure; a model is a structure that makes all of the sentences in the theory true. This specialized notion of model has been adopted by philosophers of science; on a 'structuralist' or 'semantic' conception, scientific theories are understood as structures which are used to represent real systems in nature. Philosophical debates have arisen regarding the precise extent of the resemblances between scientific models and the natural systems they represent.

MODULARITY OF MIND

A common view in recent philosophy of science is that there is no principled distinction between theoretical and observational claims, since perception itself is thoroughly contaminated by the beliefs and expectations of the observer. However, recent psychological and neurological evidence casts doubt on this latter claim and suggests, instead, that perceptual processing is to a significant extent 'cognitively impenetrable': it takes place in informationally encapsulated 'modules' that cannot be rationally influenced by beliefs or other 'central' cognitive states, or even other portions of the perceptual system.

MOHIST PHILOSOPHY

Mohist philosophy describes the broad-ranging philosophical tradition initiated by Mo Ti or Mozi (Master Mo) in the fifth century BC. Mozi was probably of quite humble origins, perhaps a member of the craft or artisan class. Early in life, he may have studied with followers of Confucius. However, he went on to become the first serious critic of Confucianism.

Mozi's philosophy was part of an organized utopian movement whose members engaged in direct social action. He was a charismatic leader who inspired his followers to dedicate themselves to his unique view of social justice. This required them to lead austere and demanding lives, as he called upon them to participate in such activities as the military defence of states unjustly attacked.

Mozi is arguably the first true philosopher of China. He was the first to develop systematic analyses and criticisms of his opponents and present carefully argued positions of his own. This led him and his later followers to develop an interest in and study of the forms and methods of philosophical argumentation, which contributed significantly to the development of early Chinese philosophy.

Mozi saw ideological differences and the factionalism they spawned as the primary source of human suffering, and he hotly criticized the familially-based ethical and political system of Confucius for its inherent partiality. In its place he advocated three basic goods: the wealth, order and the population of the state. Against the Confucians, he argued for *jian'ai* (impartial care). *Jian'ai* is often translated as 'universal love', but this is misleading. Mozi saw the central ethical problem as an excess of partiality, not a lack of compassion; he was interested not in cultivating emotions or attitudes, but in shaping behaviour. He showed remarkably little interest in moral psychology and embraced an extremely thin picture of human nature, which led him away from the widely observed Chinese concern with self-cultivation. His general lack of appreciation for psychological goods and the need to control desires and shape dispositions and attitudes also led him to reject the characteristic Confucian concern with culture and ritual.

Mozi believed human beings possess an extremely plastic and malleable nature, and he advocated a strong form of voluntarism. For several different reasons, he believed that people could be induced to take up almost any form of behaviour. First, he shared a common early Chinese belief in a psychological tendency to respond in kind to the treatment one receives. He further believed that, in order to win the favour of their rulers, many people are inclined to act as their rulers desire. Those who do not respond to either of these influences can be motivated and controlled by a system of strict rewards and punishments, enforced by the state and guaranteed by the support of Heaven, ghosts and spirits. Most important of all, Mozi believed that rational arguments provide extremely strong if not compelling motivation to act: presented with a superior argument, thinking people act accordingly.

The social and political movements of the later Mohists lasted until the beginning of the Han Dynasty (206 BC). They continued Mozi's early interests and developed sophisticated systems of logical analysis, mathematics, optics, physics, defensive warfare technology and strategy and a formal ethic based upon calculations of benefit and harm. All the philosophical concerns of the later Mohists can be found in the early strata of the *Mozi*, and seem to reflect the teachings of the tradition's founder.

PHILIP J. IVANHOE

MOLINA, LUIS DE (1535–1600)

A leading figure in sixteenth-century Iberian scholasticism, Molina was one of the most controversial thinkers in the history of Catholic thought. In keeping with the strongly libertarian account of human free choice that marked the early Jesuit theologians, Molina held that God's causal influence on free human acts does not by its intrinsic nature uniquely determine what those acts will be or whether they will be good or evil. Because of this, Molina asserted against his Dominican rivals that God's comprehensive providential plan for the created world and infallible foreknowledge of future contingents do not derive just from the combination of his antecedent 'natural' knowledge of metaphysically necessary truths and his 'free' knowledge of the causal influence – both natural (general concurrence) and supernatural (grace) – by which he wills to cooperate with free human acts. Rather, in addition to God's natural knowledge, Molina posited a distinct kind of antecedent divine knowledge, dubbed 'middle knowledge', by which God knows pre-volitionally, that is, prior to any free decree of his own will regarding contingent beings, how any possible rational creature would in fact freely choose to act in any possible circumstances in which it had the power to act freely. And on this basis Molina proceeded to forge his controversial reconciliation of free choice with the Catholic doctrines of grace, divine foreknowledge, providence and predestination.

In addition to his work in dogmatic theology, Molina was also an accomplished moral and political philosopher who wrote extensive and empirically well-informed tracts on political authority, slavery, war and economics.

MOLYNEUX PROBLEM

The origin of what is known as the Molyneux problem lies in the following question posed by William Molyneux to John Locke: if a man born blind, and able to distinguish by touch between a cube and a globe, were made to see, could he now tell by sight which was the cube and which the globe, before he touched them? The problem raises fundamental issues in epistemology and the philosophy of mind, and was widely discussed after Locke included it in the second edition of his *Essay concerning Human Understanding*.

MENNO LIEVERS

MOMENTARINESS, BUDDHIST DOCTRINE OF

The object of the Buddhist doctrine of momentariness is not the nature of time, but existence within time. Rather than atomizing time into moments, it atomizes phenomena temporally by dissecting them into a succession of discrete momentary entities. Its fundamental proposition is that everything passes out of existence as soon as it has originated and in this sense is momentary. As an entity vanishes, it gives rise to a new entity of almost the same nature which originates immediately afterwards. Thus, there is an uninterrupted flow of causally connected momentary entities of nearly the same nature, the so-called continuum (*santāna*). These entities succeed each other so fast that the process cannot be discerned by ordinary perception. Because earlier and later entities within one continuum are almost exactly alike, we come to conceive of something as a temporally extended entity even though the fact that it is in truth nothing but a series of causally connected momentary entities. According to this doctrine, the world (including the sentient beings inhabiting it) is at every moment distinct from the world in the previous or next moment. It is, however, linked to the past and future by the law of causality in so far as a phenomenon usually engenders a phenomenon of its kind when it perishes, so that the world originating in the next moment reflects the world in the preceding moment.

At the root of Buddhism lies the (never questioned) conviction that everything that has originated is bound to perish and is therefore, with the exception of factors conducive to enlightenment, ultimately a source of frustration. There is no surviving textual material that documents how this law of impermanence came to be radicalized in terms of momentariness. It seems that by the fourth century the doctrine of momentariness had already assumed its final form. Characteristically, the debate became more and more dominated by epistemological

questions, while the metaphysical aspect faded into the background.

ALEXANDER VON ROSPATT

MONISM

'Monism' is a very broad term, applicable to any doctrine which maintains either that there is ultimately only one thing, or only one kind of thing; it has also been used of the view that there is only one set of true beliefs. In these senses it is opposed to the equally broad term 'pluralism'. But it is also often contrasted with 'dualism', since so much philosophical debate has focused on the question whether there are two different kinds of thing, mind and matter, or only one.

EDWARD CRAIG

MONTAIGNE, MICHEL EYQUEM DE (1533–92)

Montaigne was a sixteenth-century French philosopher and essayist, who became known as the French Socrates. During the religious wars between the Catholics and the Protestants in France, he was a friend and adviser to leaders of both sides, including the Protestant leader Henri de Navarre, who converted to Catholicism and became King Henri IV. Montaigne counselled general toleration for all believers, a view promulgated by the new king in the Edict of Nantes (1598). His main literary work was in the form of *essais* (a word originally meaning 'attempts'), or discussions of various subjects. In these he developed various themes from the sceptical and Stoic literature of antiquity, and in his unique digressive way presented the first full statement in modern times of Pyrrhonian scepticism and cultural relativism. In particular, he presented and modernized the ancient sceptical arguments about the unreliability of information gained by the senses or by reason, about the inability of human beings to find a satisfactory criterion of knowledge, and about the relativity of moral opinions. His advocacy of complete scepticism and relativism was coupled with an appeal to accept religion on the basis of faith alone. His writings became extremely popular, and the English translation by John Florio, first published in 1603, was probably known to Shakespeare and Francis Bacon. Montaigne, whose essays provided the basic vocabulary for modern philosophy written in vernacular languages, was one of the most influential thinkers of the Renaissance, and his works are regarded as classics of literature and philosophy.

RICHARD H. POPKIN

MONTESQUIEU, CHARLES LOUIS DE SECONDAT (1689–1755)

Montesquieu, one of the greatest figures of the Enlightenment, was famous in his own century both in France and in foreign lands, from Russia to the American colonies. Later generations of French *philosophes* took for granted his concern to reform the criminal laws, to replace the Inquisition with a reign of tolerance, and to repudiate the vicious conquests of the Spaniards in the Americas. They also accepted his finding that Protestant, commercial, and constitutionalist England and Holland represented all the best possibilities of Europe; whereas Catholic, economically backward, and politically absolutist Portugal and Spain represented the worst of the Western world and constituted a warning to the French.

Although the findings and specific reforms proposed by Montesquieu were repeated by many another figure of the French Enlightenment, his work in certain respects remained unique in the circles of the most advanced thinkers. In his efforts to think systematically about politics and to do so by employing the comparative method, he stands virtually alone in his age. Other thinkers sharing his commitments resorted to the universalizing language of natural rights when they ventured into the realm of political philosophy. Or, like Voltaire, they tied their thoughts about politics to a succession of specific issues, each essay bearing so indelibly the imprint of specific time and place that there was no room for theory in their writings. Finally, as is true of Diderot or D'Alembert, many of the *philosophes* were slow to recognize what Montesquieu knew from the outset, that if Enlightenment does not extend to politics it is futile.

Steeped in Montaigne's scepticism, Montesquieu found that in the absence of absolutes there were good reasons to appreciate the 'more than/less than' and 'better than/worse than' judgments of comparative analysis. In his notebooks he commented that the flaw of most philosophers had been to ignore that the terms beautiful, good, noble, grand, and perfect are 'relative to the beings who use them'. Only one absolute existed for Montesquieu and that was the evil of despotism, which must be avoided at all costs.

Montesquieu wrote three great works, each teaching lessons about despotism and freedom, *The Persian Letters* (1721), the *Considerations of the Grandeur of the Romans and the Cause of Their Decline* (1734), and *The Spirit of the Laws* (1748).

MARK HULLIUNG

MOORE, GEORGE EDWARD (1873–1958)

G.E. Moore was one of the most influential British philosophers of the twentieth century. His early writings are renowned for his rejection of idealist metaphysics and his insistence upon the irreducibility of ethical values, and his later work is equally famous for his defence of common sense and his conception of philosophical analysis. He spent most of his career in Cambridge, where he was a friend and colleague of Russell, Ramsey and Wittgenstein.

The best-known thesis of Moore's early treatise on ethics, *Principia Ethica* (1903), is that there is a fallacy – the 'naturalistic fallacy' – in almost all previous ethical theories. The fallacy is supposed to arise from any attempt to provide a definition of ethical values. The validity of Moore's arguments is much disputed, but many philosophers still hold that Moore was right to reject the possibility of a reductive definition of ethical values. The book is also renowned for Moore's affirmation of the pre-eminence of the values of Art and Love.

Moore's later writings concern the nature of the external world and the extent of our knowledge of it. In opposition to idealist doubts about its reality and sceptical doubts concerning our knowledge of it, Moore defends 'common sense' by emphasizing the depth of our commitment to our familiar beliefs and criticizing the arguments of those who question them. But although he insists upon the truth of our familiar beliefs, he is remarkably open-minded concerning their 'analysis', which is intended to clarify the facts in which their truth consists.

THOMAS BALDWIN

MORAL AGENTS

Moral agents are those agents expected to meet the demands of morality. Not all agents are moral agents. Young children and animals, being capable of performing actions, may be agents in the way that stones, plants and cars are not. But though they are agents they are not automatically considered moral agents. For a moral agent must also be capable of conforming to at least some of the demands of morality.

This requirement can be interpreted in different ways. On the weakest interpretation it will suffice if the agent has the capacity to conform to some of the external requirements of morality. So if certain agents can obey moral laws such as 'Murder is wrong' or 'Stealing is wrong', then they are moral agents, even if they respond only to prudential reasons such as fear of punishment and even if they are incapable of acting for the sake of moral considerations. According to the strong version, the Kantian version, it is also essential that the agents should have the capacity to rise above their feelings and passions and act for the sake of the moral law. There is also a position in between which claims that it will suffice if the agent can perform the relevant act out of altruistic impulses. Other suggested conditions of moral agency are that agents should have: an enduring self with free will and an inner life; understanding of the relevant facts as well as moral understanding; and moral sentiments, such as capacity for remorse and concern for others.

Philosophers often disagree about which of these and other conditions are vital; the term moral agency is used with different degrees of stringency depending upon what one regards as its qualifying conditions. The Kantian sense is the most stringent. Since there are different senses of moral agency, answers to questions like 'Are collectives moral agents?' depend upon which sense is being used. From the Kantian standpoint, agents such as psychopaths, rational egoists, collectives and robots are at best only quasi-moral, for they do not fulfil some of the essential conditions of moral agency.

VINIT HAKSAR

MORAL JUDGMENT

Introduction

The term 'moral judgment' can refer to four distinguishable things. First, the activity of thinking about whether a given object of moral assessment (be it an action, person, institution or state of affairs) has a particular moral attribute, either general (such as rightness or badness) or specific (insensitivity, integrity). Second, the state that can result from this activity: the state of judging that the object has the attribute. Third, the content of that state: what is judged by us, rather than our judging it. And fourth, the term can be read as commendatory, referring to a moral virtue that we might also call

'moral discernment' or 'moral wisdom'. There are three principal questions regarding moral judgment. The first asks what kind of state the state of moral judgment is, and in particular whether this state is to be characterized, either wholly or in part, as a state of belief. The second is concerned with the activity of moral judgment, investigating especially the role within this activity that is played by the application of rules. The third examines the conditions under which a person is justified in making a moral judgment with a given content.

1 Cognitivism versus noncognitivism

When I think that something has a certain moral attribute (that an action is wrong, say), the state I am in seems to have features both of cognitive (belief-based) and noncognitive states. First, my moral attributions aspire to objective truth – to being true independently of my attitude towards them. For my moral attitudes can take the form 'This action is wrong, and would have been wrong even if I had approved of it', committing me to moral facts of the matter that I can be right or wrong about (see MORAL REALISM). And a state that aims to be true to independently obtaining facts must be thought of as a belief, it seems (see BELIEF). However, attributing a moral or any other evaluative feature to something seems to go beyond being in a merely cognitive state: it seems to involve orienting myself towards or away from the object of the attribution. In particular, it is often maintained that there is a certain sort of 'internal connection' between the state of moral judgment and the judge's motivation: it is part of the concept of judging something to be wrong that if I judge that it is wrong to perform this action in these circumstances, then (provided I am not weak-willed, and other things equal) I am motivated to avoid it in these circumstances (see MORAL MOTIVATION §§1–2).

Thus cognitivism about the state of moral judgment – the view that it consists essentially in a belief – seems to be supported by its objectivity-presupposing character, while noncognitivism (the denial of cognitivism) seems to be supported by the internal connection to motivation. The problem is not simply resolved by characterizing moral judgment as a compound state, comprising both a belief and a noncognitive companion state. For this would seem to require as an isolable component a pure belief that the action is wrong, and the possibility of such a belief is precisely what is at issue.

Beyond this, four main options present themselves. Each side of the dispute can either deny the claim being adduced in support of the other, or accept the claim while denying the relationship of support. Thus, first, a cognitivist might deny the internal connection, insisting that to the (unsurprisingly widespread) extent that moral judges tend to care about morality, this is only contingently true. A second, less plausible view is a noncognitivism that simply denies that moral judgments presuppose objectivity. Perhaps, as emotivism suggests, objectivity-presupposing moral judgments ought to be rejected and replaced with something else (see EMOTIVISM); it seems hard to deny that moral judgment as it actually exists does have this objectivity-presupposing character. This leaves two possibilities, each of which attempts to allow for both the objectivity-presupposing nature of moral judgment and its internal connection to motivation. According to the cognitivist internalism of John McDowell (1979), moral judgments are indeed beliefs, but beliefs of a special kind, in being internally connected to the believer's motivational states. And according to the noncognitivist objectivism of Simon Blackburn (1984), the objectivity-presupposing character of moral judgments can be explained without construing them as beliefs. The central thought here is that the attitude expressed by 'This action is wrong, and would have been wrong even if I had approved of it' can be explained as a noncognitive attitude that ranges across counterfactual as well as actual possibilities – as an attitude of approval of the action not only in the world as it is, but in the world as it would have been if I had happened to approve of the action but the world were otherwise unchanged.

It remains unclear, however, whether noncognitivism can supply a satisfactory treatment of the full range of semantic features of moral judgment-contents, and in particular, of unendorsed occurrences of moral terms, such as the first occurrence of 'wrong' in 'If blasphemy is very seriously wrong, then it is wrong to associate with blasphemers'. If not, we should be cognitivists about our actual states of moral judgment. Whether sense can be made of the objective moral facts seemingly presupposed by moral judgment is a further question – the question of moral realism (see MORAL REALISM).

2 Moral rules and deliberation

What is the role of rule-application in good deliberation about the moral attributes of things?

A widespread view is this: good moral thinking identifies correct moral principles under which the moral judge then subsumes particular instances to produce a moral verdict about them (see UNIVERSALISM IN ETHICS).

On this view, though, not much actual moral deliberation can qualify as good. Few moral judges are equipped with an exhaustive set of exceptionless moral principles by reference to which all their moral judgments are made. Most of the time, when we deliberate about whether a case instantiates a moral concept, we are engaged in an activity of moral discernment or judgment that is not simply a matter of applying a fully determinative, independently articulable rule to the case. Moreover, there seem to be good reasons not to conceive of moral deliberation as consisting ideally in the application of an exhaustive set of exceptionless moral rules. This view confronts a dilemma. Either our set of principles would be small and readily comprehensible – perhaps consisting of a single member, as in direct utilitarianism (see UTILITARIANISM) – but would need to be framed in such general terms as to make their application to even the simplest cases a difficult matter to determine; or they would be framed in terms specific enough to make the assessment of their application to particular circumstances straightforward, but would thereby need to be so numerous and highly qualified as to be unusable.

This does not yet show that good deliberation cannot consist solely in the application of rules, however. On R.M. Hare's consequentialist view, the response to this problem should be to equip ourselves with a set of familiar moral rules of thumb (for instance, 'Promise-breaking is wrong, other things being equal'), together with a meta-rule that in cases where these rules conflict we should apply a fundamental principle of direct consequentialism (see CONSEQUENTIALISM). Alternatively, Barbara Herman's Kantian theory (1985) tells us to equip ourselves with an equally familiar set of rules of moral salience – rules identifying certain features of the maxims on which actions are performed as those showing that the actions bear the burden of moral justification – together with a meta-rule that, when an action has a morally salient feature, its permissibility is to be judged in terms of the fundamental categorical imperative principle (see KANTIAN ETHICS).

3 Moral rules and justification

The views just described allow that it is proper for much of our deliberation to proceed by appealing to merely *prima facie* rules – rules specifying defeasible reasons (reasons capable of being outweighed) for making a moral attribution – but they supplement them with more fundamental, fully determinative rules governing judgment in cases where the *prima facie* rules conflict. But why should we seek rules of the fully determinative kind? The natural answer is this: good moral deliberation issues in judgments that are justified; if an all-things-considered judgment I make, in a case where my *prima facie* rules conflict, is to be justified, it cannot be arbitrary; and a judgment of mine can only be non-arbitrary if it instantiates a fully determinative rule.

When it is said that judgments are only justified by the existence of rules, two things might be intended:

(a) What makes it right to apply this concept to this object is a rule for doing so.
(b) What warrants me in judging that this concept applies to this object is a rule for doing so.

Claim (a), we might say, concerns the 'constitutive justification' of a judgment-content, whereas (b) concerns the epistemic justification of a state of judging (see JUSTIFICATION, EPISTEMIC).

Claim (a) pictures constitutive justification as consisting in the subsuming of instances under rules. This picture has been attacked, on the ground that it betrays a fallacy about rule-following (see WITTGENSTEIN, L.J.J. §10; MEANING AND RULE-FOLLOWING). Our ability to discern whether a given case falls under a rule cannot consist in our grasp of an independent meta-rule, on pain of regress. This applies to the rule 'Identify instances falling under concept *c*' as much as to any other. Proceeding correctly in the application of a concept cannot require sensitivity to an independently articulable rule which one's practice of applying the concept follows. If so, then this leaves open the possibility that there are no such further rules that justify our practice of moral concept-application. The onus is on a proponent of such rules to produce compelling examples that do square with our practice; the criticism is that they have failed to do so.

According to opponents of (a), then, there is no obstacle to the claim of 'moral pluralists' that the only defensible moral rules are *prima facie* ones. A further claim is that there are not even rules of this limited kind. This is held by moral 'particularists', who claim that there are no properties that always count as reasons for the same moral attribution. Often, the fact that an action of mine will harm someone is a reason for the wrongness of the action; but sometimes (for instance, if I am rightly administering a just punishment), it will count morally as a reason for its rightness. If so, we need to exercise a form of moral judgment that goes beyond the application of rules not only in order to determine how moral reasons relate to each other,

but to determine when a consideration counts as a moral reason (see VIRTUE ETHICS §6)

4 The virtue of moral judgment and moral epistemology

If claim (a), with its subsumptive picture of constitutive moral justification, ought to be rejected, then so should (b), concerning epistemic justification. If there need be no independently articulable rule for a correct moral attribution, then there need be no such rule for my being warranted in judging that the attribution is correct. This still leaves it open to claim a relation of mutual epistemic support between my judgments concerning *prima facie* moral principles and my judgments concerning the existence of moral reasons on particular occasions, given a coherence conception of epistemic justification (see KNOWLEDGE AND JUSTIFICATION, COHERENCE THEORY OF). However, concerning the justification of my judging that, all things considered, a particular object has a given moral attribute, it seems that we must say simply that this is justified provided it is the attribution that would be made by a person with the virtue of moral judgment or discernment.

How can one ever be warranted in believing this? If the correctness of a moral judgment depends on its endorsement by an agent with a virtue the conditions for the possession of which are not independently specifiable, then it seems that any claims to epistemic justification will amount to dubious claims of self-evidence (see INTUITIONISM IN ETHICS). To progress beyond this, we should need to be able to cite the convergence in judgment of those whom we have independent reason to identify as good moral judges.

MORAL JUSTIFICATION

Introduction

Questions of justification arise in moral philosophy in at least three ways. The first concerns the way in which particular moral claims, such as claims about right and wrong, can be shown to be correct. Virtually every moral theory offers its own account of moral justification in this sense, and these accounts naturally differ from each other. A second question is about the justification of morality as a whole – about how to answer the question, 'Why be moral?' Philosophers have disagreed about this, and about whether an answer is even possible. Finally, some philosophers have claimed that justification of our actions to others is a central aim of moral thinking. They maintain that this aim provides answers to the other two questions of justification by explaining the reasons we have to be moral and the particular form that justification takes within moral argument.

1 Three questions of justification

Questions of justification arise in moral philosophy in at least three different ways. First, it is generally taken as a central task of moral philosophy to clarify the structure of first-order moral thinking. A theory should, for example, explain 'what makes acts right'(see MORALITY AND ETHICS). Is the status of an action as morally right or wrong determined by its actual or expected consequences, by its conformity to certain rules or standards, or in some other way (see CONSEQUENTIALISM; DEONTOLOGICAL ETHICS)? Any theory that answers these questions provides us with an account of moral justification, that is to say, of justification *within* morality.

A second task of moral philosophy is to explain why we should care about morality and give its requirements priority over other considerations. This can be seen as a matter of providing a justification of morality.

Third, some philosophers have argued that it is a central aim of morality (or of some part of it, such as principles of justice) to provide a basis for justifying our actions or our institutions to one another, and that this aim provides a basis for understanding the importance of morality and for determining its

content. According to these writers, justification is an aim of morality.

2 Justification within morality

Every moral theory offers its own account of moral justification. There is, however, a more general methodological question that transcends particular accounts of 'what makes acts right', namely the question of how the claim of any such account to be the correct account of moral justification can itself be justified.

One answer to this general methodological question has been formulated by RAWLS as the method of 'reflective equilibrium'. According to this method, one begins by identifying one's 'considered moral judgments', those judgments in which one has the highest degree of initial confidence. These may be judgments of any degree of abstraction: judgments about the rightness or wrongness of particular actions, about the correctness of general moral principles, or about the moral relevance of various considerations. One then tries to find the set of principles (the account of the particular area of morality in question) that best fits with these judgments. This fit will almost certainly be imperfect, so one then proceeds to consider whether and how to modify the principles one has formulated to yield a better fit with one's considered judgments, and whether and how to modify these judgments in the light of the principles at which one has arrived. This process of revision leads to a new set of principles, and hence to a new stage of adjustments of principles and judgments. The process continues until 'equilibrium' between principles and judgments is reached; the principles one has formulated at that stage are to be taken as justified as an account of the area of morality in question.

This account of how moral principles are to be justified has been attacked, chiefly on the ground that it gives too much authority to the considered judgments with which the process begins. This is sometimes put in the form of a charge that it is circular to base an argument for a particular form of moral justification on some of the very beliefs that are to be justified. It is also objected that two people, using this same method, might arrive at quite different principles, because they began with a high degree of confidence in different sets of judgments. In reply, it can be said that the charge of circularity is misplaced, since the aim of the process is not to supply a needed justification for every moral belief we have, but rather to come up with the best general account of the subject matter. How else could we arrive at justified conclusions about a subject except by relying, at the outset, on those beliefs about that subject that seem to us most likely to be true? Moreover, in the search for reflective equilibrium no particular judgment is assumed, irrevocably, to be correct. Any reasons we might have for mistrusting particular beliefs are taken account of in the process as described, either as possible reasons for denying them the status of considered judgments to begin with or as reasons for abandoning them later when their incompatibility with the best account of our other beliefs comes to light.

3 Justification of morality

Turning now to the question of justifying morality itself, circularity looms when the bases of a proposed justification seem themselves to be moral in character. One cannot answer the question 'Why care about right and wrong?' by saying that it would be morally deficient not to. There is a dilemma here, however, since a justification for morality that appeals ultimately to values that are clearly not moral (such as those of self-interest) does not seem to give the right kind of explanation of morality's importance. It does not seem that virtuous people care about what is morally right because doing so is conducive to their self-interest.

Prichard concluded from this dilemma that moral philosophy, or at least that part of it that seeks to provide a justification of morality, 'rests on a mistake'. A less pessimistic conclusion would be that an adequate justification, or explanation, of the authority of moral requirements must appeal ultimately to considerations which are evidently relevant to morality yet have a significance which is not wholly dependent on it. The appeal of utilitarianism for some people, and the conviction of others that morality must have a basis in religion, can be explained in part by the fact that the ideas of the greatest happiness of the greatest number and of divine will appear, to members of these groups, to be the only plausible solutions to this problem. That is to say, these reasons have seemed to represent values both relevant to morality and able to supply it with the proper authority, but not (so it is claimed) dependent on it. One question is whether there are other kinds of reasons that have this status.

The task of finding such reasons is made more difficult by morality's claim to unconditional authority, and to priority over all other values. A justification for such authority seems to require starting points that are peculiarly inescapable, and it may seem that reasons grounded in what is merely one value among others could not meet this test. Accordingly, many have attempted to justify morality by showing that it is entailed, or presupposed, by something to which everyone is committed. So, for

example, KANT argued that we must take ourselves to be bound by morality in so far as we regard ourselves as rational agents, and HABERMAS has maintained that moral requirements are entailed by the idea of communication with others.

4 Justification as an aim of morality

Moral and political theories that may be broadly classed as 'contractualist' emphasize justification as an aim of morality (see CONTRACTARIANISM). They argue, for example, that our thinking about right and wrong is guided by the idea of what could be justified to others on the grounds they could not reasonably reject, or that principles of justice are to be defended on the ground of their suitability to serve as public standards for the assessment of claims against the basic institutions of a society.

These ideas are related to questions of justification of the two kinds already discussed. First, it can be claimed that the aim of justifiability to others determines the content of justification within morality. Rawls, for example, concludes that principles of justice and the basic institutions of a society must be justifiable on a basis that is independent of controversial worldviews and conceptions of the good life. Second, it can be argued that the value of being able to justify one's actions to others has the right combination of connection with morality and independence of it to serve as an explanation of the significance that morality has for us. These claims are, however, controversial. Against them it can be maintained that the idea of justifiability to others lacks sufficient importance to account for the authority of morality and that some deeper standard of right and wrong must be presupposed as a standard of justifiability.

MORAL KNOWLEDGE

One possesses moral knowledge when, but only when, one's moral opinions are true and held justifiably. Whether anyone actually has moral knowledge is open to serious doubt, both because moral opinions are so hard to justify and because there is reason to think moral opinions are expressions not of belief (which might be evaluated as true or false) but of taste or preference. A successful defence of the view that people do have moral knowledge requires assuaging these doubts. Attempts in this direction standardly emphasize the respects in which our moral opinions, and the evidence we have for them, are analogous to the opinions and evidence we have concerning non-moral matters, such as logic, mathematics, science, psychology and history. In the process they attempt to show that we do have good reason to think some of our moral opinions are true.

MORAL LUCK

The term 'moral luck' was introduced by Bernard Williams in 1976 to convey the idea that moral status is, to a large extent, a matter of luck. For example, that Bob grows up to be vicious and Tom to be virtuous depends very much on their different family conditions and educational background. Following Williams, Thomas Nagel widened the scope of moral luck. The position taken by both stands in stark contrast to the widely-held view, influenced by Kant, that one is morally accountable only for what is under one's control, so that moral accountability is not a matter of luck. This idea is so deeply entrenched in our modern concept of morality that rejecting it would call for a rethinking and reformulation of the most basic notions of morality. Some have argued that the paradox of moral luck provides a strong reason to abandon traditional moral theories, and lends support to virtue ethics.

DANIEL STATMAN

MORAL MOTIVATION

Introduction

Questions about the possibility and nature of moral motivation occupy a central place in the history of ethics. Philosophers disagree, however, about the role that motivational investigations should play within the larger subject of ethical theory. These disagreements surface in the dispute about whether moral thought is necessarily motivating – 'internalists' affirming that it is, 'externalists' denying this.

The disagreement between externalists and internalists reflects a basic difference in how the

subject matter of ethics is conceived: externalism goes with the view that ethics is primarily about the truth of theories, construed as sets of propositions, while internalists see morality as a set of principles meant to guide the practical deliberations of individual agents. Internalists interpret questions of objectivity in ethics as questions of practical reason, about the authority of moral principles to regulate our activities. Here controversy has centred on whether the authority of practical principles for a given agent must be grounded in that agent's antecedent desires, or whether, instead, practical reason can give rise to new motivations.

There are also important questions about the content of moral motivations. A moral theory should help us to make sense of the fact that people are often moved to do the right thing, by identifying a basic motive to moral behaviour that is both widespread and intelligible, as a serious source of reasons. Philosophers have accounted for moral motivation in terms of self-interest, sympathy, and a higher-order concern to act in accordance with moral principles. But each of these approaches faces difficult challenges. Can egoistic accounts capture the distinctive character of moral motivation? Can impartial sympathy be integrated within a realistic system of human ends? Can we make sense of responsiveness to moral principle, as a natural human incentive?

1 Internalism and externalism

Internalism states that moral considerations are necessarily motivating for those who grasp them. The most common version of this position is the claim that sincere acceptance of a moral judgment implies that the person who accepts it has some motive – not necessarily overriding – for compliance with the judgment. Externalists deny this, insisting that one might sincerely accept a moral judgment without any corresponding motivation. On this view, psychological questions about human motivation are completely distinct from issues about the truth of moral judgments or the nature and constitution of moral facts (see MORAL JUDGMENT §1; MORAL REALISM §1).

The categories 'internalism' and 'externalism' were introduced only in the middle of the twentieth century. It is often unclear how exactly these categories are to be understood, inviting confusion about their precise extension. (Which moral judgments are supposed to be motivationally effective? How are we to understand the notion of a motive that is present, but not necessarily overriding?) So it is often hard to classify moral philosophers as internalists or externalists as such.

Nevertheless, David Hume is presumably giving voice to an internalist point of view when he makes central to his theory the idea that 'morals excite passions, and produce or prevent actions' (*A Treatise of Human Nature* 1739/40). In characteristic internalist fashion, Hume interprets this idea as placing the important constraint on an account of moral distinctions that it must explain how grasping moral distinctions could immediately give rise to passions and actions, in the way it seems to do. By contrast, the hermetic distinction drawn by John Stuart Mill in *Utilitarianism* (1861), between the proof of the principle of utility and the sanctions for compliance with it, suggests an externalist position. On this position, it would be possible to accept a moral principle without having any tendency to act in accordance with it; the question of the truth of a moral principle is thus taken to be completely distinct from the psychological issue of whether and how the principle can be rendered effective in people's motivations (see HUME, D. §10; MILL, J.S. §§7–8).

2 Implications

The issue of moral motivation is a crux in discussions about the nature and status of moral judgments and moral values. Noncognitivists, who hold that moral judgments express emotions or preferences rather than report genuine truths, often start out by affirming that moral judgment is directly motivating, a version of internalism (see MORAL UDGMENT §1; EMOTIVISM). Underlying the position that only noncognitivism can explain this fact is the assumption that the cognitive states through which we grasp judgments capable of genuine truth are motivationally inert.

In a more metaphysical vein, irrealists or error theorists, who deny the reality of moral values in the world, similarly argue from internalist assumptions. Real moral values would have to have the distinctive property of affecting the will directly. But, it is argued, items with this property would be mysterious – utterly unlike the other kinds of things with which we are familiar in the world – and so we should be reluctant to include them in the inventory of reality (see MORAL REALISM).

Philosophers who wish to resist these conclusions may either accept internalism, and try to show that

cognitivist or realist views can account for the motivational effects of ethical reflection, or reject internalism (see MORAL REALISM). Those who pursue the second option need not deny that people are often motivated to do what they judge to be morally right or good. Like Mill, however, they insist that motivations of this kind are not necessarily built into moral reflection; rather it is the task of moral education to supply them.

The interest of this dispute lies in its connection with fundamentally divergent ways of thinking about moral objectivity and the subject matter of ethics. Externalism goes naturally with the view that moral philosophy is essentially about moral theories, construed as sets of propositions setting out what it is morally right or good to do. On this conception, questions of objectivity in ethics turn primarily on the truth of the propositions that make up competing moral theories. But whether a given proposition is true or false seems independent of the psychological question of whether and how people may be moved to act in accordance with it. Taking this approach seriously, we may be led to the conclusion that the true moral theory should be esoteric, so that the theory itself provides good reasons for discouraging people from accepting it, a conclusion countenanced by SIDGWICK and other utilitarians.

Internalist approaches, by contrast, conceive of moral philosophy as dealing with common principles for public moral discourse and practical deliberation. On this view, the issue of objectivity in ethics is conceived primarily as an issue of practical reason, about the title of moral principles to regulate our activities. Moral reflection is accordingly thought of as a form of practical deliberation, yielding verdicts about what is to be done, and questions about the truth of moral propositions assume a subsidiary role. If we conceive of the subject in this way, then some form of internalism will seem inevitable, since it is the distinguishing mark of practical deliberation that it affects the will directly. Furthermore, it will hardly make sense to suppose that the criteria of right defined by the correct moral theory should be esoteric, since the kind of objectivity aimed at primarily in ethical theory is precisely an objectivity within practical reason (see PRACTICAL REASON AND ETHICS).

3 Reason and desire

Within the internalist camp, there are striking disagreements about the degree to which the motivational consequences of practical reason effectively constrain our philosophical options. On one side are the Humeans, who hold that practical reasoning must always be grounded in the non-cognitive psychological states of individual agents – what Bernard WILLIAMS calls their 'subjective motivational sets'. Combined with internalism, this view has the consequence that moral principles are hostage to antecedent, empirical facts about the motivational sets of the agents to whom the principles apply. This conclusion in turn exerts some pressure in the direction of relativism, since motives to comply with moral principles may, as a matter of empirical fact, fail to show up in the subjective sets of all agents (see MORAL RELATIVISM).

On the other side, Kantians deny that empirical facts about people's subjective motivational sets place substantive restrictions on the content or normative force of moral principles. They point out that any theory of practical reason must allow for the phenomenon of motivational irrationality (see AKRASIA). Thus I may fail to take steps that I know to be necessary if I am to attain some end that I hold dear. The principle that I ought to pursue those means that are necessary for realizing my ends does not entail that I will necessarily be motivated accordingly, but only that I will be motivated accordingly in so far as I am rational. This has been pointed out by Christine Korsgaard. If she is right, then it cannot be inferred from the fact that a given agent lacks an empirical motive for compliance with a candidate principle that the principle is not binding on the agent, since it is possible that the agent is irrational. To decide whether that is the case, however, we will need to determine – in a way that is not circumscribed by antecedent facts about people's motives – the content of principles of practical reason.

A central question in this dispute concerns the role of desires in the explanation of motivation. Humean resistance to the idea of practical principles that are not grounded in people's subjective sets stems from the idea that motivation is essentially a noncognitive orientation to the world. Kantians – most notably including Thomas NAGEL (1970) – have granted that motivation always involves a state of desire, but suggested that reasoning in accordance with practical principles may give rise to new desires, so that the validity of such principles for a given agent need not be constrained by the items already contained in that agent's subjective motivational set.

4 Explanation and justification

However this dispute is resolved, it cannot be denied that the disposition to respond to moral principles is reliably awakened and strengthened in the normal course of human psychological development. Furthermore, moral reasons often weigh

heavily with people in their practical deliberations, leading them to take remarkable steps to avoid doing what would be wrong. It seems a reasonable constraint on moral theories that they should help us to make sense of these facts. A theory on which it appeared utterly mysterious that people naturally respond to moral considerations and take them seriously in their deliberations would be to that extent implausible.

What is needed is an account of the content of our moral incentives. Moral theories typically identify some common pattern of motivation, such as sympathy or self-interest, and try to show how motivations of that type might lead people to comply with principles of right, as the theory characterizes them. In practice, human motives are heterogeneous, complex and fluid; why should we suppose that there is any general account to be had of our responsiveness to moral considerations? This supposition is linked to two controversial normative assumptions. First, there is the assumption that moral considerations hang together in such a way that a uniform account can be provided of what makes actions morally wrong (in terms, for instance, of the effects of the actions on general utility, or the failure of universalizability). Philosophers who accept this assumption naturally expect to find a complementary general pattern of moral motivation, while those who deny it – some virtue theorists, perhaps – will be more sceptical.

Second, it is commonly assumed that modern morality aspires to a kind of objectivity within practical reason, providing public principles that make claims on virtually all agents. Here controversy centres not so much on whether morality represents itself as authoritative in this way, as on its title to such authority. How this controversy is resolved will depend in part on whether we can identify incentives to moral behaviour that are both widespread in human nature and intelligible as serious sources of reasons, for the availability of such common motivational structures would seem a necessary condition for the objective authority of morality.

It would not, however, be sufficient. If Nietzsche and Freud are right, for instance, then there are common motivational structures at the root of moral responsiveness, involving internal mechanisms for enforcing compliance with moral norms that draw on the redirection of aggressive impulses back against the self (see Nietzsche, F. §§8–9; Freud, S.). These accounts suggest a ready explanation of the urgency with which moral demands are invested in the deliberations of many agents; indeed, they have the further advantage of being able to explain the characteristic pathologies of the moral life, such as moralistic forms of extreme self-denial. But the explanations provided by these accounts seem to undermine rather than to vindicate the authority of morality, suggesting that the common patterns of moral motivation are essentially harmful for the individuals subject to them.

This shows that the authority of morality will depend not just on the availability of a common incentive to moral behaviour, but on the content of the common incentive that is identified. An account of moral motivation congenial to morality's normative ambitions would, at a minimum, identify a motive to moral behaviour that can be cultivated without necessarily causing dire psychological harm to the individual who has the motive. Beyond this, an effective moral motive should be capable of being integrated within an agent's overall system of ends, so as to produce a stable and self-reinforcing personality.

5 Egoism and self-interest

Very few philosophers accept egoism, construed as the psychological thesis that our motives are uniformly self-interested. This bald thesis flies in the face of the many occasions on which people act without any apparent concern for their own interests, however broadly conceived. Even when our motives are self-interested, the specification of our interests would seem to presuppose some core of nonegoistic concerns, a point well made by Joseph Butler (see Butler, J.; Egoism and altruism §3).

Still, self-interest is an undeniably widespread and powerful pattern of motivation, and this makes it an obvious candidate in terms of which to reconstruct moral concern. Thus, suppose that compliance with moral principles could be shown to conduce to the long-term interest of each individual. We would then have a ready explanation to hand of the ease with which moral incentives emerge in the course of psychological development, and of the urgency with which moral considerations present themselves in practical deliberation: these phenomena would reflect the natural concern of humans for their own wellbeing, and the equally natural use of practical reason in the service of this concern. This explanation would in turn support rather than undermine the authority of morality. Those who make morality regulative of their activities would thereby achieve integration and stability of personality in an exemplary degree, since morality, far from being inimical to our other interests, would represent the condition for their effective pursuit.

This broadly Hobbesian strategy for understanding morality rests on the idea that each of us benefits enormously from the availability of certain public

goods – such as peace, security, and trustworthiness – that can be secured only through general compliance with moral norms (see Hobbes, T. §5). Discussions of the strategy have become highly sophisticated, drawing on advances in the theory of rational choice (see Rational choice theory). But the increasing sophistication of its formulation cannot compensate for the inadequacy of the strategy as an account of moral motivation. The strategy might show that something like moral norms make claims on all of us. But to the extent that our incentive to comply with these norms is self-interest, the norms themselves seem to lose their distinctively moral character, for it is part of our understanding of moral requirements that they are to be followed even when it is inexpedient for us to do so. The problem is made vivid by the figure of the prospective 'free rider', who asks why they should comply with social norms when sufficiently many other people follow them to secure the public goods of cooperation. However this question may be answered, the very fact that it needs to be asked shows that the prospective free rider is not an ordinary moral agent at all.

6 Altruism and sympathy

A genuinely moral agent – as opposed to an egoist – is altruistic, in the sense of having some immediate concern for the interests of others. Furthermore, the capacity for sympathetic identification seems natural to human beings; it is the rare person who is not directly moved by exposure to human suffering, and this tendency to sympathetic response can be nurtured through moral education. For these reasons, many have followed Hume and Schopenhauer in taking sympathy to be the paradigmatic moral motivation (see Hume, D. §10; Schopenhauer, A.; Moral sentiments).

If sympathy is to play this role, however, then it will need to be corrected and refined. Actual sympathy is notoriously partial and erratic, directed (for instance) at those individuals with whom one has some personal connection, whereas morality seems to demand impartiality of response. Thus, whether morality requires that I help a given person should not depend just on whether I happen to know them, but also (for instance) on the comparative urgency of the claims of others. The standard way to deal with this problem is to subject the mechanism of sympathetic identification to the discipline of impartial reflection. One is to adopt the perspective of an informed spectator, abstracting from one's knowledge of one's own position in the world, and treating each person's welfare as equally important; the morally right action is what sympathy, refined by this procedure of reflection, would then lead one to approve of. Though liable to many different interpretations, this general approach to moral motivation has been associated traditionally with utilitarianism (see Impartiality; Utilitarianism).

The utilitarian approach yields an impersonal conception of ethical impartiality, on which moral requirements take an agent-neutral rather than agent-relative form. Consider the familiar moral prohibition on murder. This is ordinarily understood as an agent-relative requirement, proscribing my killing another person even if by doing so I could prevent a number of other murders. But a prohibition of this kind would not survive utilitarian impartial reflection. Once we abstract from our knowledge of our local position in the world, it is no longer possible to sustain a proprietary concern for the character of our own actions. When sympathy is subjected to a filter of impersonal reflection, it can only endorse requirements that are agent-neutral in form, and hence capable of being accepted and acted on by any other agent as well (an injunction to prevent murder, say, instead of the conventional agent-relative prohibition on killing people oneself). In this way, the impersonal interpretation of impartiality defines a standpoint that is available to be occupied by any moral agent.

Questions arise, however, about the authority and motivational effectiveness of the claims made from this point of view. To take the latter first, it is supposed to be an advantage of the utilitarian approach that it accounts for moral motivation in terms of the familiar operations of sympathy. But there is a vast difference between the immediate, impulsive sympathy that develops naturally in human beings and the impersonal concern to maximize the good. The utilitarian claims that sympathy is transformed into a responsiveness to agent-neutral reasons as a result of moral reflection, but one may wonder whether sympathy, thus transformed, remains a natural pattern of motivation.

As for authority, the question is whether impersonal sympathy can be integrated into a person's system of ends. It gives us a standing first-order aim – the maximization of the good – which is set over against our other first-order aims, and likely to conflict fundamentally with them (given the demands that the maximization of the good notoriously imposes on individuals). The result is that we must either radically curtail the pursuit of our ordinary interests for the sake of morality, or resign ourselves to living in a way that is not morally justifiable. Utilitarians reply that morality is a hard thing, and that we should not expect to be able to accommodate its demands within the contours of ordinary bourgeois life. But the difficulty of integrating impersonal sympathy within a normal system of human ends is likely to raise a doubt about

the authority of a morality construed in these terms: by what right does it demand this degree of sacrifice of us?

7 Principle-dependent motives

Kantian approaches typically trace moral concern to a higher-order motive, such as the concern to act only in ways that are permitted by moral principles (see KANTIAN ETHICS). Motives of this type will sometimes give an agent first-order ends, namely when moral principles require a certain course of action (keeping a promise, say). But when moral principles do not impose requirements in this way it will be open to agents to pursue their first-order ends while at the same time completely satisfying their higher-order moral concern. Morality regulates our first-order pursuits, but because the moral motive does not automatically supply a standing first-order end it is not inevitably in conflict with those pursuits, and so the possibility of integrating moral concern within a realistic system of human ends is left open.

Whether this possibility is realized will depend on the content of moral principles. If those principles instructed us always to maximize the good, then they would in effect determine a standing first-order end. In that case the higher-order concern to act in ways that are permitted by moral principles might be as difficult to integrate with our other ends as impersonal sympathy would be. But Kantians reject such maximizing interpretations of morality, taking moral requirements to derive from reflection on the universalizability of our aims, and contending that these universality procedures yield specific agent-relative obligations that function as limiting conditions on our activities.

The idea that morality supplies a higher-order motive invites the charge that it is self-indulgent, reflecting a fastidious concern for one's own virtue rather than a direct responsiveness to the needs of others. Further, the involvement of moral principles in Kantian moral motivation seems to deny moral worth to spontaneous and heartfelt actions, and threatens to erect an alienating screen of reflection between moral agents and their projects. A more fundamental question is whether the motive of duty can be rendered intelligible, as a natural human incentive. Why should the concern to act in ways that are universalizable emerge so readily in moral development, and present itself to us as a serious source of reasons?

To this, Kant replies that the motive of duty is constitutively rational, and that acting on it enables us to realize the supreme good of autonomy (see KANT, I. §9). Somewhat less ambitiously, T.M. Scanlon observes that people commonly want to be able to justify their conduct to others on grounds that could not reasonably be rejected, arguing that moral principles tell us what we have to do to satisfy this familiar desire. Either of these strategies might derive support from the readiness with which people respond to 'golden rule' arguments, in which we invite them to consider what it would be like to change positions with those who would be affected by their actions. This phenomenon suggests that the concern to act in ways that are universalizable may be a powerful and *sui generis* pattern of human motivation.

MORAL PARTICULARISM

Moral particularism is a broad set of views which play down the role of general moral principles in moral philosophy and practice. Particularists stress the role of examples in moral education and of moral sensitivity or judgment in moral decision-making, as well as criticizing moral theories which advocate or rest upon general principles. It has not yet been demonstrated that particularism constitutes an importantly controversial position in moral philosophy.

MORAL PSYCHOLOGY

Introduction

Moral psychology as a discipline is centrally concerned with psychological issues that arise in connection with the moral evaluation of actions. It deals with the psychological presuppositions of valid morality, that is, with assumptions it seems necessary for us to make in order for there to be such a thing as objective or binding moral requirements: for example, if we lack free will or are all incapable of unselfishness, then it is not clear how morality can really apply to human beings. Moral psychology also deals with what one might call the psychological accompaniments of actual right, or wrong, action, for example, with questions about the nature and possibility of moral weakness or self-deception, and with questions about the kinds of motives that ought to motivate moral agents. Moreover, in the approach to ethics known as 'virtue ethics' questions about right and wrong action merge with questions about the motives, dispositions, and abilities of moral agents, and moral psychology plays a more central role than it does in other forms of ethical theory.

1 Psychology and the possibility of morality

We can divide the main traditional concerns of moral psychology as a distinctive philosophical discipline into questions about the psychological assumptions necessary to the validity of morality, or moral rules, in general, and questions about the psychological concomitants or underpinnings of particular actions evaluated either as good/right or as bad/wrong. The question of whether human beings have free will or freedom of choice (see FREE WILL) naturally falls within the first of these areas. If human beings lack free will, then, it has over the millennia typically (though not universally) been assumed, they cannot be held responsible for their actions and cannot be bound by moral obligations any more than are animals or small children. Thus those who have systematically elaborated one or another view of moral right and wrong have usually thought it necessary to defend, or at least explicitly assume, the existence of human free will, or freedom of choice.

In the first instance this standardly involves saying something about free agency in relation to universal causal/nomic determinism. If the world is universally governed by causal or physical laws, then it is unclear how anyone could possibly have behaved otherwise than they in fact did, and so have been responsible for what they did. So defenders of (objective) morality typically feel called upon either to argue that human beings are in important ways not subject to iron-clad causal determination, or else to show that causal determinism does not in fact deprive us of free will (see DETERMINISM AND INDETERMINISM).

Another metaphysical or quasi-metaphysical issue that looms large in moral psychology concerns the human capacity for morality. Most moral codes and moral philosophies require, for example, that people occasionally put aside self-interest in the name of honour, fairness, decency, compassion, loyalty or the general good. But if one believes in psychological egoism, one will hold that people lack the capacity for these forms of self-sacrifice, and it then becomes problematic whether human beings really have the obligations that various non-egoistic moral views/theories claim that they do (see EGOISM AND ALTRUISM).

But even if one rejects both psychological and ethical egoism, there are moral-psychological issues about how much morality can fairly be demanded of people. These issues arise especially in connection with utilitarianism (see UTILITARIANISM) and Kantianism (see KANTIAN ETHICS). Utilitarianism is usually stated in a 'maximizing' form that treats it as a necessary and sufficient condition of right action that one do the best/most one circumstantially can to advance the happiness of humankind (or sentient beings). But such a doctrine seems to entail that if one is in a position to relieve the suffering, hunger or disease of others, one is morally obliged to do so, even if that means giving up one's own life plans and most of what one really cares about in life. The traditional utilitarian moral standard is thus very demanding, and some philosophers have questioned whether morality can properly, or, one might say, fairly, require so much of people. In particular, it may be wondered whether most people have the capacity to live up to such a stringent morality as is presented by maximizing utilitarianism.

Certain doctrines of Kantian ethics can likewise be seen as going against the grain of human nature or capacities, not by demanding too much of a sacrifice of self-interest, but by laying down rather stringent or narrow psychological conditions for the moral admirability of actions. According to Kant, if one helps someone in need or in trouble out of fellow-feeling or friendship, one's act lacks all moral worth, because it was not performed out of a sense of duty and respect for the moral law. And many ethical thinkers have either implicitly or explicitly held such a view of moral virtue to be too narrow and out of keeping with realistic human psychology,

and have argued that certain primary, immediate or natural motives such as compassion or friendly feeling not only have moral worth, but can often be even more praiseworthy than a cool appeal to duty or to something as abstract as the moral law. But Kantians question the durability and reliability of mere feeling or emotion, and there remains considerable debate in this area.

2 Psychology and moral judgment

Another topic that has recently occupied moral psychologists and ethicists is the relevance of so-called 'moral emotions' to moral judgments. Some philosophers have considered the validity of one or another moral theory to depend, in part, on whether people tend to feel guilty for violating its dictates. But others have held that there are situations where guilt is inevitable, but that that fact constitutes no sort of evidence of wrongdoing. Indeed, it is sometimes argued that the question of whether guilt for some action is *appropriate* or *justified* is separate from the issue of whether that action was actually wrong (Greenspan 1988). (Is it, for example, appropriate to feel guilty about injuries one caused in a traffic accident that was someone else's fault entirely?) Other philosophers, however, seek to connect the moral emotions with morality by arguing that the seeming *ineradicability* of our emotions of anger and resentment provides some sort of underpinning for human judgments about justice and injustice, praiseworthiness and blameworthiness (see MORALITY AND EMOTIONS; MORAL SENTIMENTS).

In addition, moral psychologists concern themselves with various forms of situational moral failure, such as self-deception and weakness of will (see AKRASIA). The very existence of these phenomena is often questioned on grounds of their paradoxical character. If one is motivated to deceive oneself about some difficult matter (for example, the needs of one's children), how can one possibly succeed unless one knows what it is one has to deceive oneself about – in which case, in what way is one actually deceived? Similarly, if moral weakness, or weakness of will more generally, means allowing anger or passion to lead one to act against one's better judgment, is it not natural to reconfigure our understanding of what is happening so as to suppose that the reasons for anger or passion warp one's sense of what really is best (for one) – in which case, in what way has one actually acted against one's (however momentary) better judgment?

Both weakness of will and self-deception are, therefore, inherently problematic, and moral psychology has sought ways of either making sense of these moral phenomena or showing them definitively to be incoherent and consequently impossible (see, for example, Pears 1984). Either 'solution' has bearing on the moral assessment of actions (and desires). If self-deception is possible, what sort of blame attaches to it when it leads to bad consequences (for example, neglect of children)? Should it be counted as a deliberate, intentional act; or it is more like negligence, or heedlessness? But if self-deception is not possible, then what masquerades as such may be more like intentional wrongdoing, and perhaps even more blameworthy, than it initially appears (see SELF-DECEPTION, ETHICS OF). Then too, if weakness of will is not possible, many cases we are inclined (at most) partially to excuse on grounds of weakness may be cases in which the agent is actually compelled, psychologically, to act wrongly – or else perhaps momentarily ignorant of the difference between right and wrong. Such conclusions are bound to affect the character and/or severity of the blame or punishment directed at those who initially seemed to be acting weakly.

Another set of issues in moral psychology arises within the tradition of moral theory known as virtue ethics, which treats issues of moral psychology as essential to our understanding of right and wrong action (see VIRTUE ETHICS). Thus, rather than basing morality on moral rules or on the production of 'good consequences', Aristotelian virtue ethics denies the possibility of universal moral rules and thinks of the virtuous individual as someone who intuitively perceives what is right or noble in various situations and, fairly effortlessly, acts accordingly. To that extent, the Aristotelian tradition in virtue ethics approaches the idea of moral rightness in some measure indirectly, by focusing on the character, habits and abilities of the virtuous individual who tracks rightness in thought and actions.

In addition, there is a more radical tradition of virtue ethics in which the moral evaluation of actions and moral rules is directly derived from characterizations of good and bad motivation and how these may be expressed or realized in someone's actions. Perhaps the best-known historical example of such an approach can be found in Plato's *Republic* (Book IV), where it is said that good actions are those that enhance or support the health and harmony of the soul (see PLATO §14).

A more recent and 'purer' example (because it does not mention anything like the Form of the Good) can be found in James Martineau's *Types of Ethical Theory.* Martineau ranks all human motives on an absolute scale – for example, compassion is placed above ambition, the latter above sexual desire, and the latter, in turn, above vindictiveness – and claims that right action is action that comes from the higher or highest motive operating in any

given situation of moral choice. This then allows moral rules of thumb to be derived from generalizations about which motives are likely to operate in various morally familiar situations.

These varying virtue-ethical approaches put moral psychology at the very centre of ethics. However, for the foreseeable future, the chief role of moral psychology will probably be as a discipline ancillary to, rather than as the main focus of, moral theory.

MORAL REALISM

Introduction

Moral realism is the view that there are facts of the matter about which actions are right and which wrong, and about which things are good and which are bad. But behind this bald statement lies a wealth of complexity. If one is a full-blown moral realist, one probably accepts the following three claims.

First, moral facts are somehow special and different from other sorts of fact. Realists differ, however, about whether the sort of specialness required is compatible with taking some natural facts to be moral facts. Take, for instance, the natural fact that if we do this action, we will have given someone the help they need. Could this be a moral fact – the same fact as the fact that we ought to do the action? Or must we think of such a natural fact as the natural 'ground' for the (quite different) moral fact that we should do it, that is, as the fact in the world that makes it true that we should act this way?

Second, realists hold that moral facts are independent of any beliefs or thoughts we might have about them. What is right is not determined by what I or anybody else thinks is right. It is not even determined by what we all think is right, even if we could be got to agree. We cannot make actions right by agreeing that they are, any more than we can make bombs safe by agreeing that they are.

Third, it is possible for us to make mistakes about what is right and what is wrong. No matter how carefully and honestly we think about what to do, there is still no guarantee that we will come up with the right answer. So what people conscientiously decide they should do may not be the same as what they should do.

1 Realism, objectivism, cognitivism

These three terms are hard to keep separate, but it is worth the effort. Cognitivism is the claim that moral attitudes are cognitive states rather than noncognitive ones. The distinction between cognitive and noncognitive states is not clear; the best way of drawing it is by appeal to the distinction between two 'directions of fit'. Beliefs, which are the paradigm examples of a cognitive state, have one direction of fit; desires, which are the paradigm examples of a noncognitive state, have the other. A belief, that is, has to fit the world; the world is given, as it were, and it is the belief's job to fit that world, to get it right. A desire is not like that; the desire's job, if anything, is to get the world to fit it, to make things be the way it wants them to be. Crucially, a desire is not at fault if things are not as it wants them to be; a belief is at fault if things are not as it takes them to be. The question whether moral attitudes are cognitive states or noncognitive ones is the question whether they have the direction of fit of a belief, or that of a desire. They could, of course, be complex states with a mixture of both; but noncognitivism is the view that moral attitudes have either wholly or partly the direction of fit of a desire. This is normally expressed more briefly as the view that moral attitudes either are, or at least contain, desires; to think an action right is a sort of 'pro-attitude', and pro-attitudes are wantings (see Belief; Desire; Moral Judgment §1).

Realists, believing that there are distinct moral facts, are likely to be cognitivists, since the appropriate attitude to a fact is belief rather than desire. It is for this reason that the opposition to realism is normally called 'noncognitivism'. Realists, holding there to be moral facts, maintain for that reason that moral attitudes are beliefs; noncognitivists, holding that moral attitudes either are or include desires, claim for that reason that there are no facts to be the objects of those attitudes.

Objectivism is harder to distinguish from realism, since the two are very closely linked. Objectivity is something to do with independence from us. Realism, as characterized above, combines three theses: a distinctness thesis, a metaphysical thesis and an epistemological thesis. The metaphysical thesis is the claim that moral facts are objective. If moral facts are independent in some way, what exactly is it that they are independent of? To say 'independent of us' is little help at best, and straightforwardly wrong at worst. Moral facts concern agents and actions, which are human matters, and so they are not completely independent of us; if we were different, different actions would be wrong. The phrasing used above, 'independent of any beliefs and thoughts we might have about them', attempts to be more precise, at the cost of excluding too much. Is the limitation involved in 'about them' justified? If not, what other limitation would be better? This matter is very difficult to resolve (see OBJECTIVITY).

Realism, on this showing, is a complex of claims. The distinctness claim carves out a distinctive subject matter for ethics. The independence claim tells us something about the sort of fact that ethics is concerned with. The epistemological claim tells us that we have a less than perfectly secure grip on those facts. Moral realists have, however, generally been willing to say that we are capable of moral knowledge, even if we do not achieve it very often. They would all agree that are we capable of justified moral beliefs (if they are cognitivists).

Readers should be aware that the characterization of moral realism is a matter of hot debate. In particular, as well as the sort of account offered here, there is a form of realism that, taking its start from the claim that there are facts of the matter in ethics, and so moral truths, holds that there must therefore be 'truth-makers' – things that make the truths true. In the moral case, what makes moral truths true must be the possession of moral properties by suitable agents and actions. Realism, so understood, is the commitment to moral properties and relations as no less 'real' than other properties. It is possible, however, to combine these two strands of realist thinking without strain.

2 Arguments for realism, and an outline of its history

Corresponding to the three elements of realism, there are three things commonly urged by realists in favour of their position. In different ways, they all suggest that we should take seriously the way things initially appear to us. Realists try to hold that things are as they appear, despite noncognitivist arguments that they cannot possibly be. This is sometimes called 'the appeal to phenomenology'.

First, realists claim that moral thought appears to have its own subject matter, distinct from science and all natural inquiry. Second, they argue that moral judgment appears to be an attempt to determine a matter of fact that is independent of any beliefs we might have about it; the fact is one thing, and what we think about it another. Third, realists hold that moral judgment presents itself to the judger as risky and fallible. When facing a difficult choice, especially, we have a sense of thin ice; we know that, with the best will in the world, the view we come to may be wrong. Only the second two of these three claims may properly be termed 'phenomenological'.

Most moral theorists have been realists, from Plato and Aristotle through Price and Hutcheson to Sidgwick and Mill, and then, in the twentieth century, to Moore and the intuitionist tradition (see INTUITIONISM IN ETHICS). It is the opposition to realism that needs to be documented. Here the patron saint of noncognitivism is Hume, whose work flowered, though altered in many respects, in the noncognitivist tradition of Stevenson, Ayer and Hare (see EMOTIVISM). Leading contemporary noncognitivists are Blackburn and Gibbard.

Advances in the philosophy of language, philosophy of mind and philosophy of science in the 1960s and 1970s persuaded many that the noncognitivist arguments against realism, which had dominated the intellectual scene since 1930, were less powerful than they had appeared. Two quite distinct forms of moral realism emerged, American and British. (This means only that most proponents of the first form are American, and most proponents of the second are British.) In the next two sections, the differences between these two positions will be charted in three areas: metaphysics, epistemology and theory of motivation.

3 American moral realism

Metaphysics. American moral realists are naturalists: they suppose that moral facts are either natural facts or configurations of natural facts (see NATURALISM IN ETHICS). As suggested in the initial summary, it is possible that the fact that if I do this I will have helped someone and harmed nobody else is the fact that I ought to do this action. Perhaps, however, the moral fact is more complex than this natural fact (and than any other single natural fact), without this meaning that it is not some combination of natural facts. If so, those natural facts will have to be combined in the right sort of way – in the sort of way that they are here – if they are together to make the moral fact that I ought to do this action. Then the moral fact will be identical with this configuration of natural facts.

This form of naturalism in ethics is often, though not always, accompanied by some form of consequentialism. A certain sort of natural fact is a moral fact because there is a relation between that fact and certain consequences (see CONSEQUENTIALISM). Naturalism in ethics is now a live option again because of a growing sense that G.E. Moore's 'open question' argument is flawed (see MOORE, G.E.).

Epistemology. American moral realists, seeing moral facts as natural facts, suppose that they are knowable in whatever ways natural facts can be known, including science. To identify those facts as moral facts, we will need to combine the best scientific theory with the best moral theory.

Theory of motivation. How is it possible to reconcile the claim that moral facts are natural facts with the widespread sense that moral facts have an intrinsic authority – that they make demands on us to which we should respond, whatever our personal choices and preferences? This 'intrinsic authority' is hard to understand in any detail. Perhaps the best attempt is Kant's distinction between categorical and hypothetical imperatives (see KANT §1; KANTIAN ETHICS). Moral imperatives such as, 'Help those less fortunate than you', are categorical, in the sense that one cannot escape their relevance to oneself by saying, 'I just don't care very much about that sort of thing'. By contrast, a hypothetical imperative such as, 'Use fresh eggs to make an omelette', has no grip on those who just do not care about how their omelettes taste.

However we understand it, the idea of the authority of moral facts does not sit easily with ethical naturalism. Natural facts, however configured, do not seem able to have any such authority over the will (see MORAL MOTIVATION §§1–2). American realists generally respond to this by doubting the claim that any fact could have that sort of authority. The world, whether in its moral or its more obviously natural clothes, is one whose grip on us depends on our bringing to it a sort of moral concern (which will have been the product either of evolution or of education). If we lack that concern, we will be unmotivated by moral distinctions, even though we will be still perfectly capable of discovering which actions are right and which are wrong. To know the right is one thing, and to bend one's will to it another. Moral judgment is cognitive; it is the discovery of facts. But facts are motivationally inert; whether one is motivated by them depends not so much on them as on what one cares about. So moral imperatives are hypothetical, despite appearances.

In these thoughts, American realists adopt what is sometimes called a 'Humean' theory of motivation. Neither belief nor desire alone can lead to action; only a combination of the two can do that. (For an action we need two mental states, one with each direction of fit.) Moral facts are the objects of belief. No such belief can motivate alone; for there to be an action, the agent must have some desire or preference as well as the belief. Moral facts cannot motivate in their own right, thus; their ability to make a difference to how we act depends upon the independent contribution of a desire. This being so, they cannot have such a thing as an intrinsic authority over us; for whether they can make a difference to how we act depends on something over which they have no control (see PRACTICAL REASON AND ETHICS §2).

4 British moral realism

The British variety of moral realism denies everything that the American variety claims.

Metaphysics. British moral realism is non-naturalist: moral facts are not natural facts, nor are they are natural configurations of natural facts. They may be non-natural configurations of natural facts, but that is another matter. Natural facts are relevant to moral ones, of course, since they are the reasons why actions are right or wrong. It follows from this that any two situations that are naturally indistinguishable must be morally indistinguishable (see SUPERVENIENCE). But this sort of supervenience is a far cry from any identity between the natural and the moral.

In terms of the characterization of moral realism given earlier, the British thus attribute far greater distinctness to moral facts, considering them to be metaphysically distinct from natural ones. The Americans have a harder task in showing what is distinctive about the moral, though not an impossible one. They can say, for instance, that moral facts are distinguished by their subject matter, or by the sort of configuration of natural facts that they are.

Epistemology. If moral facts are not natural facts, the normal methods of finding out how things are will not suffice for the discovery of the moral. Admittedly, British realists have been prone to talk of seeing that an action is right. But it appears that they mean by this neither that rightness is visible, nor that there is a moral sense in addition to the normal five senses. Talk of seeing that the action is right is intended to echo Aristotle's remark that right and wrong are not matters of rules so much as of the nature of the case before us, and that to discern what is right we have to concentrate on the details of the present situation (see VIRTUE ETHICS §6). They deny, therefore, that moral judgment is a matter of subsumption, of bringing the present case under some moral rule. Moral judgment is the application of concepts, but those concepts are not

rules. Indeed, it is characteristic of British realists to be sceptical about the very possibility of moral rules or principles. For them, moral judgment is a matter of recognizing the reasons for action as they present themselves in the present case, and responding to them as such (see UNIVERSALISM IN ETHICS). This sort of recognition is not perceptual, but it is cognitive and practical at once – for what one is recognizing is a reason for action, that is, a normative state of the world.

Theory of motivation. American realists are 'externalists' about moral judgment. They hold that the ability of a moral judgment to motivate, that is, to make a difference to how one acts, is dependent on the presence of a quite different mental state, namely some sort of desire. British moral realists are generally 'internalists', holding that a moral judgment motivates in its own right, and does not get its ability to affect action from a desire that is present at the same time (see MORAL MOTIVATION §1). To make this out, they have to reject the standard Humean picture of motivation, though they do not agree among themselves about quite how to do this. Wiggins and McDowell hold that action does require a combination of belief and desire, but that in the moral case it is belief that leads and desire that follows. Dancy suggests that it is belief alone that motivates, since mere recognition of relevant reasons should be enough for action; he sees desire as a state of being motivated (by the reasons), not as what motivates. Either way, the suggestion that there are genuinely normative and non-natural facts is combined with the claim that recognition of these facts motivates in its own right, in a way that is not dependent on the presence of an independent desire.

This raises problems. The first is that Humeanism is more or less received wisdom; so the British are fighting an uphill battle in rejecting it. The second is that it is very hard to make sense of the idea of a state of the world, or fact, that stands in some intrinsic relation to the will. It is normal to think that facts are motivationally inert; to recognize them is one thing, and to bend the will to them another. The British hold that the response to the fact, which we call recognition, is itself motivational. The preferred way of doing this is by appeal to the 'dispositional conception of value'. This conception is inspired by a supposedly similar dispositional conception of colour: a red object is one that is disposed to cause in us a characteristic sort of experience (see COLOUR, THEORIES OF). Similarly, a valuable object is conceived as one which is disposed to elicit a certain response from us, an inclination of the will. As such, it is not totally independent of us, since it consists (at least partly) in a certain relation to us; and this means that it is not fully objective, if objectivity is to be understood in terms of independence from us. But it is still objective in a weak sense, since value can still be conceived as there for us to recognize and there whether we recognize it or not.

There are two difficulties with this appeal to dispositions. The first is that the analogy with colours is hotly disputed. The second is that, in order to keep values in the world, their objectivity has had to be diminished. For some, this weaker conception of objectivity is hardly to be distinguished from subjectivity.

5 Realism and minimalism

In this entry, realism has been seen as a combination of three distinct theses. But there is an alternative account of what realism is that sees it as nothing more than a claim about truth. The realist, on this account, holds that moral statements are capable of truth, and indeed that some are true. If we say this, we can still distinguish between realism and objectivism in ethics. Realism is the claim that moral judgments are sometimes true; objectivism is the claim that the sort of truth they have is objective truth.

We can distinguish two sorts of opposition to this form of realism. The first accepts that moral statements are capable of truth, but holds that all are false (see MORAL SCEPTICISM); the second holds that truth is not the appropriate form of success for a moral judgment, and that we would do better to think of them as sincere or insincere, or as more or less well connected with other judgments, or as ones that we ourselves would agree with. One should not try to combine these two sorts of opposition.

Crispin Wright has suggested that, if this is what is at issue between realism and noncognitivism, the matter will be quickly resolved in favour of realism. In his view, the mere fact that moral discourse is assertive, and that moral utterances are governed by norms of warranted assertibility, is enough to establish that we make no mistake in calling some true and others false. The question should not be, then, whether moral judgments are capable of truth, since everyone really admits that they are. Instead, the debate about realism should focus on other questions. According to Wright, among these questions are:

(1) Is it a priori that differences of moral opinion can only be explained in terms of divergent input, unsuitable conditions or malfunction (such as prejudice and dogma)?
(2) Do the supposed moral facts serve to explain anything at all? Suppose that they explain (some of) our moral beliefs. Do they explain anything else in a way that is not mediated by our beliefs?

> That is to say, do moral facts directly explain anything about how the world goes?

Wright suggests that we only get a 'full-blooded' moral realism if our answer to these questions is 'yes'. There will, therefore, be degrees of realism, and in a way the question is not whether we should be realists, but what sort of realists we should be. How far should our realism go?

6 Arguments against realism

Since realism comes in different forms, arguments against it are more likely to attack some particular form than to attack realism as such. The main difficulties for the American and the British realist schools have already been mentioned. In both cases they were metaphysical. The Americans have difficulty in keeping moral facts both natural and moral. The British have difficulty in explaining how the world can be other than 'motivationally inert'.

The two general challenges to realism that are most often mentioned are those made by John Mackie and Gilbert Harman. Harman asks what, if anything, is explained by moral facts that cannot be equally well explained by moral beliefs. If moral belief alone is enough for all such explanations, why suppose that the facts exist in addition to the beliefs? The facts appear to be explanatorily redundant. We might suggest that at least the facts explain the beliefs, but Harman replies that the beliefs can be equally well explained in other ways, for example, by appeal to upbringing and education. This leaves the facts explaining nothing; they are mere metaphysical danglers, hanging in the air and not related to anything else at all. We are better off without such things. (This is different from Wright's view above, because Wright allows that moral facts could explain moral beliefs; he only asks whether they could explain anything else 'directly'.)

Mackie (1977) suggests that values, if they existed, would be very peculiar things, unlike anything else in the universe; so queer are they that, if they existed, we would need a special faculty of moral perception or intuition to perceive them. Their queerness lies in the idea that an objective value would necessarily be pursued by anyone who recognized it, because such values have 'to-be-pursuedness' built into them. Even if such things are possible, which nobody influenced by Hume would allow, something of that sort is of a different order from anything else with which we are acquainted.

Mackie also asks about the supposed relation between moral facts and natural facts. We ordinarily say, for instance, that an action was wrong because it was cruel. But 'just what *in the world* is signified by this "because"?' (1977: 41; original emphasis). Not only is there the wrongness and the cruelty, but also a totally mysterious 'consequential link' between the two.

These arguments of Mackie's are answered in different ways by the different varieties of realism. The Americans deny the possibility of 'to-be-pursuedness'; the British admit it, but try to explain it by appeal to the dispositional theory of value. As for the mysterious 'consequential link', both sides would, in their different ways, try to say that the wrongness is somehow 'constituted' by the cruelty.

MORAL RELATIVISM

Introduction

Often the subject of heated debate, moral relativism is a cluster of doctrines concerning diversity of moral judgment across time, societies and individuals. Descriptive relativism is the doctrine that extensive diversity exists and that it concerns values and principles central to moralities. Meta-ethical relativism is the doctrine that there is no single true or most justified morality. Normative relativism is the doctrine that it is morally wrong to pass judgment on or to interfere with the moral practices of others who have adopted moralities different from one's own. Much debate about relativism revolves around the questions of whether descriptive relativism accurately portrays moral diversity and whether actual diversity supports meta-ethical and normative relativism. Some critics also fear that relativism can slide into nihilism.

1 Descriptive relativism

From the beginnings of the Western tradition philosophers have debated the nature and implications of moral diversity. Differences in customs and

values the Greeks encountered through trade, travel and war motivated the argument attributed to the sophist Protagoras in Plato's *Theaetetus*: that human custom determines what is fine and ugly, just and unjust (see PROTAGORAS). Anthropologists in the twentieth century have emphasized the fundamental differences between the moralities of small-scale traditional societies and the modern West. For example, many traditional societies are focused on community-centred values that require the promotion and sustenance of a common life of relationships, in contrast to both the deontological morality of individual rights and the morality of utilitarianism that are the most prominent within modern Western moral philosophy. Within this philosophy itself moral diversity is represented by the debates between utilitarians and deontologists, and more recently criticism of both camps by defenders of virtue theory and communitarianism (see DEONTOLOGICAL ETHICS; UTILITARIANISM; VIRTUE ETHICS; COMMUNITY AND COMMUNITARIANISM). Such differences have motivated the doctrine of *descriptive relativism*: that there exists extensive diversity of moral judgment across time, societies and individuals, and that it concerns central moral values and principles.

Critics of descriptive relativism argue that it fails to account for important moral similarities across cultures such as prohibitions against killing innocents and provisions for educating and socializing the young. A relativist response given by Michael Walzer is to argue that shared norms must be described in an extremely general way and that once one examines the concrete forms they take in different societies, one sees significant variety, for example, in which persons count as 'innocent'. The descriptive relativist might go so far as to assert that no significant similarities exist, but an alternative position is that broad similarities exist that are compatible with significant differences among the moralities human beings have held.

Critics of descriptive relativism also argue that many moral beliefs presuppose religious and metaphysical beliefs, and that these beliefs, rather than any difference in fundamental values, give rise to much moral diversity (see RELIGION AND MORALITY). Also, differences in moral belief across different societies may not arise from differences in fundamental values but from the need to implement the same values in different ways given the varying conditions obtaining in these societies. One relativist reply is that while such explanations apply to some moral disagreements, they cannot apply to many others, such as disagreements over the rightness of eating animals or the moral status of the foetus or the rightness of sacrificing an innocent person for the sake of a hundred more.

2 Meta-ethical relativism

The most heated debate about relativism revolves around the question of whether descriptive relativism supports *meta-ethical relativism*: that there is no single true or most justified morality. There is no direct path from descriptive to meta-ethical relativism; the most plausible argument for meta-ethical relativism is that it is part of a larger theory of morality that best explains actual moral diversity.

Critics of meta-ethical relativism point out that moral disagreement is consistent with the possibility that some moral judgments are truer or more justified than others, just as disagreement among scientists does not imply that truth is relative in science. Some relativists are unimpressed by the analogy with science, holding that disagreements about the structure of the world can be sufficiently radical to undermine the assumption that there is an absolute truth to be found. This defence of meta-ethical relativism amounts to founding it upon a comprehensive *epistemological relativism* that expresses scepticism about the meaningfulness of talking about truth defined independently of the theories and justificatory practices of particular communities of discourse.

An alternative relativist response is to take a nonrelativist stance towards science and to drive a wedge between scientific and moral discourse. Defenders of such a *morality-specific meta-ethical relativism* argue that scientific disagreements can be explained in ways that are consistent with there being a nonrelative truth about the structure of the physical world while moral disagreements cannot be treated analogously. For example, much scientific disagreement may be traced to insufficient or ambiguous evidence or distortions of judgment stemming from personal interests. Relativists have argued that such explanations will not work for moral disagreements such as the ones mentioned above concerning the eating of animals, abortion, and the sacrifice of an innocent to save more lives.

In offering alternative explanations of moral disagreement, morality-specific relativists tend to adopt a 'naturalistic' approach to morality in the sense that they privilege a scientific view of the world and fit their conceptions of morality and moral disagreement within that view. They deny that moral values and principles constitute an irreducible part of the fabric of the world and argue that morality is best explained on the theory that it arises at least in part from custom and convention. On Wong's view (1984), for example, a good part of morality arises out of the need to structure and regulate social cooperation and to resolve conflicts of interest. Meta-ethical relativism

is true because there is no single valid way to structure social cooperation.

Morality-specific relativism divides into *cognitive* and *non-cognitive* versions (see MORAL JUDGMENT §1). On C.L. Stevenson's emotivist view, for example, moral discourse merely expresses emotion and influences the attitudes and conduct of others (see EMOTIVISM). Cognitive relativists, such as Mackie, Harman, Foot and Wong, interpret moral judgments as expressing belief, on the grounds that moral judgments are often argued or judged true or false on the basis of reasons. Within cognitive relativism, there are those who believe that there is no single true morality because more than one morality is true, and those who believe that there is no single true morality because all are false. J.L. Mackie (1977) represents the latter camp, on the ground that while morality actually arises out of custom and convention, the meanings of moral terms presuppose a mistaken reference to *sui generis* properties that provide everyone with a reason for acting according to morality. Other cognitive relativists see no need to construe moral terms as containing a reference to nonexistent properties and instead tie their cognitive content to certain standards and rules.

According to such a standards relativism, moral language is used to judge and to prescribe in accordance with a set of standards and rules. Different sets of standards and rules get encoded into the meaning of ethical terms such as 'good', 'right' and 'ought' over time, and into individuals, groups, or societies in such a way that two apparently conflicting moral beliefs can both be true. Though under a relativist analysis the beliefs express no conflicting claims about what is true, they do conflict as prescriptions as to what is to be done or as to what kinds of things are to be pursued. The disagreement is purely pragmatic in nature, though parties to the disagreement may not be aware of this if they erroneously assume they share the relevant standards.

Another crucial question for the standards relativist concerns *whose* standards and rules apply when someone makes a moral judgment. Suppose that Jones makes a moral judgment about what Smith ought to do, but that the standards Jones applies to guide his own conduct are not the same as the standards Smith uses to guide hers. One possibility is that Jones uses Smith's standards to judge what she ought to do. Another possibility offered by Harman in some of his writing about relativism is that one must judge others by standards one shares with them. His theory is that morality consists of implicit agreements for the structuring of social cooperation. Moral judgments implying that the subjects have a reason to do what is prescribed make sense only as prescriptions based on what the speakers and subjects (and the intended audience of the judgments) have agreed to do. Other standards relativists observe that people use their own standards in judging the conduct of others, whether or not they believe these others share their standards.

There are *radical* and *moderate* versions of meta-ethical relativism. Radical relativists hold that any morality is as true or as justified as any other. Moderate relativists, such as Foot (1978) and Wong (1984), deny that there is any single true morality but also hold that some moralities are truer or more justified than others. On Wong's view, for instance, certain determinate features of human nature and similarities in the circumstances and requirements of social cooperation combine to produce universal constraints on what an adequate morality must be like. It may be argued, for example, that a common feature of adequate moralities is the specification of duties to care and educate the young, a necessity given the prolonged state of dependency of human offspring and the fact that they require a good deal of teaching to play their roles in social cooperation. It may also be a common feature of adequate moralities to require of the young reciprocal duties to honour and respect those who bring them up, and this may arise partly from the role that such reciprocity plays in ensuring that those who are charged with caring for the young have sufficient motivation to do so. Such common features are compatible with the recognition that adequate moralities could vary significantly in their conceptions of what values that cooperation should most realize. Some moralities could place the most emphasis on community-centred values that require the promotion and sustenance of a common life of relationships, others could emphasize individual rights, and still others could emphasize the promotion of utility.

3 Normative relativism

Does meta-ethical relativism have substantive implications for action? *Normative relativism* – the doctrine that it is morally wrong to pass judgment on or to interfere with the moral practices of others who have adopted moralities different from one's own – is often defended by anthropologists, perhaps in reaction to those Western conceptions of the inferiority of other cultures that played a role in colonialism. It also has application to disagreements within a society such as that concerning the morality of abortion, where the positions of the disputing parties seem ultimately to be based on fundamentally different conceptions of personhood.

As in the case of descriptive and meta-ethical relativism, however, there is no direct path from metaphysical to normative relativism. One could

hold consistently that there is no single true morality while judging and interfering with others on the basis of one's own morality. Wong has proposed a version of normative relativism consistent with the point that nothing normative follows straightforwardly from meta-ethical relativism. Meta-ethical relativism needs to be supplemented with a liberal contractualist ethic to imply an ethic of nonintervention. A liberal contractualist ethic requires that moral principles be justifiable to the individuals governed by these principles. If no single morality is most justified for everyone, *liberal normative relativism* may require one not to interfere with those who have a different morality, though the requirement of noninterference may not be absolute when it comes into conflict with other moral requirements such as prohibitions against torture or the killing of innocents (see LIBERALISM).

4 Relativism and moral confidence

A reason why relativism has been feared is the thought that it could easily slide into moral nihilism. Could one continue living according to one's moral values, which sometimes require significant personal sacrifice, if one can no longer believe that they are truer or more justified than other values that require incompatible actions? One relativist response is that one may reasonably question the importance of certain features of one's morality upon adopting a view of their conventional origin. Consider that duties to give aid to others are commonly regarded as less stringent than duties not to harm them. Gilbert Harman has proposed that this difference results from the superior bargaining position of those with greater material means in the implicit agreement giving rise to morality. Those with lesser material means may reasonably question this feature of morality, if they are persuaded of Harman's explanation. Notice, however, that it is not merely the supposition that this feature arose from convention that may undermine one's confidence in it. With regard to other features of one's morality, one may adopt a relativist view of them and continue to prize them simply because they are as good as any other and because they help to constitute a way of life that is one's own.

Admittedly, people who condemn torture and unremitting cruelty as an offence against the moral fabric of the world may possess a certitude not available to relativists and may find it easier to make the personal sacrifices morality requires. Moral certitude has its own liabilities, however, and has itself contributed to the unremitting cruelty that human beings have inflicted upon each other.

MORAL SCEPTICISM

Scepticism in general is the view that we can have little or no knowledge; thus moral scepticism is the view that we can have little or no moral knowledge. Some moral sceptics argue that we cannot have moral knowledge because we cannot get the evidence necessary to justify any moral judgments. More radical moral sceptics argue that we cannot have moral knowledge because in morality there are no truths to be known. These radical sceptics argue either that moral judgments are all false because they erroneously presuppose the real existence of 'objective values', or that moral judgments aim to express feelings or influence behaviour instead of stating truths. Critics of moral scepticism, in turn, argue that in at least some cases moral judgments aim to state truths, some of these judgments are in fact true, and we have enough evidence to say that we know these moral truths.

MORAL SENSE THEORIES

In *Leviathan* (1651), Thomas Hobbes argued that since good and evil are naturally relative to each individual's private appetites, and man's nature is predominantly selfish, then morality must be grounded in human conventions. His views provoked strong reactions among British moral philosophers in the seventeenth and eighteenth centuries. Moral sense theories comprise one set of responses. A moral sense theory gives a central role to the affections and sentiments in moral perception, in the appraisal of conduct and character, and in deliberation and motivation. Shaftesbury and Francis Hutcheson argued that we have a unique faculty

of moral perception, the moral sense. David Hume and Adam Smith held that we cultivate a moral sensibility when we appropriately regulate our sympathy by an experience-informed reason and reflection.

JACQUELINE TAYLOR

MORAL SENTIMENTS

Moral sentiments are those feelings or emotions central to moral agency. Aristotle treated sentiments as nonrational conditions, capable of being moulded into virtues through habituation. The moral sense theorists of the Enlightenment took sentiments to provide the psychological basis for our common moral life. Kantian approaches deny the primacy of sentiments in moral personality, and treat moral sentiments as conditioned by our rational grasp of moral principles.

A central issue is whether moral sentiments incorporate moral beliefs. Accounts which affirm a connection with moral beliefs point to the complex intentionality (object-directedness) of such states as resentment or indignation. Against this, some observe that moral emotions may be felt inappropriately.

Of special interest are the sentiments of guilt and shame. These seem to reflect different orientations towards moral norms, and questions arise about the degree to which these different orientations are culturally local, and whether either orientation is superior to the other.

MORALITY AND EMOTIONS

Emotions such as anger, fear, grief, envy, compassion, love and jealousy have a close connection to morality. Philosophers have generally agreed that they can pose problems for morality in a variety of ways: by impeding judgment, by making attention uneven and partial, by making the person unstable and excessively needy, by suggesting immoral projects and goals.

The place of emotions in moral theories depends on whether they are conceived of merely as impulses without thought or intentional content, or as having some sort of cognitive content. Plato argued that emotions form a part of the soul separate from thought and evaluation, and moved, in the course of his writings, from a sceptical view of their contribution to morality to a more positive appraisal. Aristotle connected emotions closely with judgment and belief, and held that they can be cultivated through moral education to be important components of a virtuous character. The Stoics identified emotions with judgments ascribing a very high value to uncontrolled external things and persons, arguing that all such judgments are false and should be removed. Their cognitive analysis of emotion stands independent of this radical normative thesis, and has been adopted by many philosophers who do not accept it.

Modern theories of emotion can be seen as a series of responses and counter-responses to the Stoic challenge. Descartes, Spinoza, Kant and Nietzsche all accepted many of the Stoics' normative arguments in favour of diminishing the role played by emotions in morality; they differed, however, in the accounts of emotion they proposed. Focusing on compassion or sympathy, Hutcheson, Hume, Rousseau, Adam Smith and Schopenhauer all defended the role of some emotions in morality, returning to a normative position closer to Aristotle's (though not always with a similarly cognitive analysis).

Contemporary views of emotion have been preoccupied with the criticism of reductive accounts that derive from behaviourist psychology. By now, it is once again generally acknowledged that emotions are intelligent parts of the personality that can inform and illuminate as well as motivate. Philosophers' views have been enriched by advances in cognitive psychology, psychoanalysis and anthropology. Feminist accounts of emotion differ sharply, some insisting that we should validate emotions as important parts of moral character, others that emotions shaped by unjust conditions are unreliable guides.

MARTHA C. NUSSBAUM

MORALITY AND ETHICS

Morality is a distinct sphere within the domain of normative thinking about action and feeling (see Normativity); the whole domain, however, is the subject of ethics.

How should the moral sphere be characterized? The three most influential suggestions are that morality should be characterized by its *function*, by the *supremacy* of the moral, or by the distinctive moral *sentiments*. It is plausible that moral codes have a social function, such as that of maintaining

beneficial cooperation; but it does not seem an a priori truth. In contrast, it may be true a priori that moral obligations are supreme – accepting an obligation as moral is accepting that it should be carried out whatever else may be said against doing so. But even if this is a priori, it does not provide a criterion for demarcating the moral. A better characterization takes an obligation to be moral if and only if certain sentiments, those invoked in blame, are justified towards an agent who fails to comply with it.

This provides a criterion for demarcating the moral, but only if the sentiments can be identified. The sentiment at the core of blame is sometimes held to be a species of anger – indignation, for example. However it seems that one may feel the sentiment involved in guilt or blame without feeling indignation. A view deriving from Hegel's conception of wrongdoing may be more accurate. Whereas indignation disposes to aggressive restorative action, the sentiment of blame itself disposes to withdrawal of recognition, expulsion from the community. Punishment can then be seen, with Hegel, as a route whereby recognition is restored.

Criticisms of morality are broadly of two kinds, though they often overlap: that moral valuation rests on incoherent presuppositions, and that morality is a dysfunctional system. The leading source of the first kind of criticism (and one source of the second) is Nietzsche; in contemporary philosophy related ideas are developed by Bernard Williams. One of Williams' criticisms centres on something which does indeed seem to be presupposed by moral valuation, at any rate in modern moral thought: that moral obligations exist independently of one's desires and projects yet of themselves give one a reason to act. Other doubts about the coherence of the moral focus on a conception which, again, may be distinctively modern – being associated particularly with some forms of Protestant Christianity and with Kant; the conception takes it that all are equally autonomous and that the only true worth is moral worth. Criticisms of this conception occur (in different ways) in Nietzsche's treatment of modern morality and in Hegel's treatment of what he calls *Moralität*.

The idea that morality is dysfunctional, that blame and guilt deny life or impose pain without securing compensating gains, has considerable influence in contemporary culture (as does the idea that they are compromised by the interests of those who can shape them). Such criticism must come from a conception of ethical value, and assume that there is an alternative to morality. Unless one believes in the possibility of a communal life unmediated by any disciplinary forces at all, the assumption being made must be that there could be a discipline which was better, ethically speaking, than the discipline of guilt and blame.

MORE, THOMAS (1477–1535)

Thomas More was a classical, biblical and patristic scholar, an author in many genres, a lawyer who became Lord Chancellor, a humanist 'born for friendship' according to Erasmus, a widowed husband who remarried and could not decide which wife he loved more, a father who established a 'school' with the best of tutors in his home so that his daughters could have the same formal education (denied to women) as his son, and a martyr who refused to recognize Henry VIII as head of the church in England and was therefore beheaded by the king he had vindicated against Martin Luther. With his *Utopia* he coined a word and inspired subsequent writers to imagine both ideal and non-ideal societies.

MOTOORI NORINAGA (1730–1801)

Motoori Norinaga was a pivotal figure in Japan's 'Native Studies' or 'National Learning' (*kokugaku*) movement. An accomplished philologist, he helped decipher the idiosyncratic eighth-century orthography of the Japanese chronicle of history and myth, the *Kojiki* (Records of Ancient Matters). This was part of his broader scholarly project of defining the nature of the ancient Japanese sensitivity or 'heart-and-mind' (*kokoro*). In so doing, he articulated an influential religious philosophy of Shintō and an axiology of traditional Japanese values, which he considered as primarily emotivist and aesthetic.

See also: Japanese philosophy; Shintō

THOMAS P. KASULIS

MOZI (5th century BC)

Mozi was the first philosopher to question the ideas of Confucius. Scholarly debate centres around the issue of whether Mozi was a 'weak' or a 'strong' utilitarian, an 'act' or 'rule utilitarian', and whether he was a 'language utilitarian' or rather placed the religious authority of a personalized Heaven at the centre of his system. He is noteworthy for being the first thinker to develop a tripartite methodology for verifying claims to knowledge and for attacking the Confucian emphasis on ritual and the centrality of the family as the basis for social and political action.

ROBIN D.S. YATES

MULTICULTURALISM

Multicultural political philosophy explores ways of accommodating cultural diversity fairly. Public policies often have different consequences for members of different cultural groups. For example, given the importance of language to culture, and the role of the modern state in so many aspects of life, the choice of official languages will affect different people very differently. Similar issues arise concerning the cultural content of education and the criminal law, and the choice of public holidays. To avoid policies that create unfair burdens, multicultural theory turns to abstract inquiries about such things as the relation between culture and individual wellbeing, or the relation between a person's culture and the appropriate standards for judging them. Multiculturalism raises related questions for democratic theory also. Culture may be important to deciding on appropriate units of democratic rule and to the design of special mechanisms for representing minorities within such units. Each of these questions is made more difficult in the context of cultures that reject the demands of liberty or equality. The challenge for philosophers is to develop a principled way of thinking about these issues.

ARTHUR RIPSTEIN

MURDOCH, IRIS (1919–99)

Iris Murdoch was an Oxford moral philosopher and a prolific novelist. Her philosophy was marked by a strong sense of the moral significance of our inner lives: the quality of our seeing, feeling and imagining is significant, both in itself and as a background for our active lives. Moral effort, Murdoch believed, consists mainly in the struggle against our natural egoism. She thought ethics should discuss the techniques of this struggle and took a particular interest in the role art might play in such a context. Insisting on the irreducible plurality of the moral 'field of force', Murdoch did not develop a moral theory; yet she also believed that moral experience is haunted by a sense of unity. Her thought revolved around this tension. Inspired by Plato, she referred to this unity as 'Good' and understood it as a distant perfect reality present in imperfect human lives as a baffling but magnetic force. The phenomena and problems that had Murdoch's philosophical interest were also explored in her fiction, despite her insistence that she was not a philosophical novelist.

THOMAS NORGAARD

MUSIC, AESTHETICS OF

The aesthetics of music comprises philosophical reflection on the origin, nature, power, purpose, creation, performance, reception, meaning and value of music. Some of its problems are general problems of aesthetics posed in a musical context; for example, what is the ontological status of the work of art in music, or what are the grounds of value judgments in music? Other problems are more or less peculiar to music, lacking a clear parallel in other arts; for example, what is the nature of the motion perceived in music, or how can the marriage of music and words best be understood?

Attempts to define the concept of music generally begin with the fact that music involves sound, but also posit such things as cultural tradition, the fulfilment of a composer's aims or the expression of emotions as essential features of music. Perhaps any plausible concept, though, has to involve the making of sounds by people for aesthetic appreciation, broadly conceived. In deciding what is meant by a musical work, further considerations come into play, such as might lead to the identification of it with a sound structure as defined by a given composer in a particular musico-historical context.

In what sense can a piece of music be said to have meaning? Some hold it has meaning only internally – in its structure as an arrangement of melodies, harmonies, rhythms and timbres, for instance – while others have claimed that its meaning lies in the communication of things not

essentially musical – such as emotions, attitudes or the deeper nature of the world. The most popular of these beliefs is that music expresses emotion. This is not to say, however, that the emotion expressed in a work is necessarily experienced by those involved in its composition or performance: composers can create peaceful or furious music without themselves being in those states, and the same goes for the performance of such music by performers. Also, the emotions evoked in listeners seem of a different nature from those directly experienced: negative emotions expressed in music do not preclude the audience's appreciation, and in fact commonly facilitate it. Ultimately, a work's expressiveness should be seen as something directly related to the experience of listening to that work. Music is often said to have value primarily in so far as it is beautiful, its beauty being whatever affords pleasure to the listener. But the quality of a work's expressiveness, its depth, richness and subtlety, for example, also seems to form an important part of any value judgment we make about the work.

NÆSS, ARNE (1912–)

As professor of philosophy in Oslo between 1939 and 1970, Arne Næss contributed to a strengthening of the position of philosophy in Norwegian academic life. During the German occupation (1940–5) he played an active part in the resistance movement. In the 1940s and 1950s he was the inspiration for and centre of a group of students of philosophy and social science, the 'Oslo School', whose members became influential in the later development of these fields. His philosophical thinking passed through an early 'scientistic' period of radical empiricism to 'possibilist' and pluralist views, and an undogmatic scepticism. After resigning his professorship in 1970, he became the protagonist of a version of ecological philosophy, 'deep ecology'. He has always been an admirer of Spinoza and has also sought inspiration in Spinozism for his ecological philosophy.

INGEMUND GULLVÅG

NAGEL, ERNEST (1901–85)

Ernest Nagel was arguably the pre-eminent American philosopher of science from the mid-1930s to the 1960s. He taught at Columbia University for virtually his entire career. Although he shared with Bertrand Russell and with members of the Vienna Circle a respect for and sensitivity to developments in mathematics and the natural sciences, he endorsed a strand in the thought of Charles S. Peirce and John Dewey that Nagel himself called 'contextual naturalism'. Among the main features of contextual naturalism is its distrust of reductionist claims that are not the outcomes of scientific inquiries.

Nagel's contextual naturalism infused his influential, detailed and informed essays on probability, explanation in the natural and social sciences, measurement, history of mathematics, and the philosophy of law. It is reflected, for example, in his trenchant critiques of Russell's reconstruction of the external world and Russell's epistemology as well as cognate views endorsed at one time or another by members of the Vienna Circle.

ISAAC LEVI

NAGEL, THOMAS (1937–)

The comprehensiveness of Thomas Nagel's approach to philosophy sets him apart among late-twentieth-century analytic philosophers. Nagel develops a compelling analysis of the fundamental philosophical problems, showing how they result from our capacity to take up increasingly objective viewpoints that detach us from our individual subjective viewpoints as well as from the viewpoints of our community, nation and species. Our essentially dual nature, which allows us to occupy objective as well as subjective viewpoints, poses unsolvable problems for us because subjective and objective viewpoints reveal conflicting facts and values. Our ability to undertake increasingly detached viewpoints from which objective facts come into view indicates that we are contained in a world that transcends our minds; similarly, our ability to examine our values and reasons from a detached or impartial objective viewpoint implies that moral values are real in the sense that they transcend our personal motives and inclinations. Yet Nagel also holds that our capacity for objective thought is limited by the fact that we cannot detach ourselves completely from our own natures in our attempts either to know our world or to act morally. Subjective facts are equally a part of reality and our moral outlook is essentially the outlook of individual agents with personal and communal ties. Consequently, Nagel argues against any form of reductionism which holds that only objective facts and values are real or which attempts to explain subjective facts and values in terms of objective ones.

NARRATIVE

Narrative, in its broadest sense, is the means by which a story is told, whether fictional or not, and regardless of medium. Novels, plays, films, historical texts, diaries and newspaper articles focus, in their different ways, on particular events and their temporal and causal relations; they are all narratives in the above sense. Accounts of mathematical, physical, economic or legal principles are not. A narrower sense of narrative requires the presence of a narrator mediating between audience and action, and contrasts with imitative discourse wherein the action is presented directly, as in drama. The boundary between narration narrowly construed and imitation is disputed, some writers arguing that apparently imitative forms are covertly narrated.

Attempts have been made to characterize fictional narratives in linguistic terms; another view is that fictions are things which have certain (intended or actual) effects on the audience. Theorists of narrative have mostly concentrated on narratives of the fictional kind and have developed a complex taxonomy of the various narrative devices. Recently, pressure has been placed on the distinction between historical and fictional narrative by those who believe that history is nothing distinct from the various and conflicting narrative versions we have. It has also been argued that value accrues to an agent's life and acts when those acts conform to a conception of that life as exemplifying narrative.

GREGORY CURRIE

NATION AND NATIONALISM

No one observing political events in the world today could deny the continuing potency of nationalism. Many of the most intractable conflicts arise when one national community tries to break away from another, or when two such communities lay claim to the same piece of territory. Yet to outsiders the basis for such conflicts often seems mysterious. People are prepared to fight and die for their nation, yet what exactly is this 'nation' that commands such loyalty? Why should it matter so much that a person is governed by leaders drawn from one community rather than from another?

Philosophers are often inclined to dismiss nationalism as having no rational basis, but as resting merely on tribal instincts and brute emotions. Such a response overlooks the different forms that nationalism has taken: in particular, the contrast between authoritarian nationalism, which allows national cultures to be imposed by force and which may justify acts of aggression against neighbouring peoples, and liberal nationalism, which upholds the rights of individuals to form political communities with those with whom they feel identified and to protect their common culture. We need to examine carefully the arguments that have been advanced by nationalist thinkers in order to decide which form of nationalism, if any, is rationally defensible.

DAVID MILLER

NATIVISM

Traditional empiricism claims that the mind is initially equipped only with the capacity for experience and the mechanisms that make it possible for us to learn from experience. Nativists have argued that this is not enough, and that our innate endowment must be far richer, including information, ideas, beliefs, perhaps even knowledge.

Empiricism held the advantage until recently, partly because of a misidentification of nativism with rationalism. Rationalists such as Descartes and Leibniz thought nativism would explain how a priori knowledge of necessary truths is possible. However, the fact that something is innate does not establish that it is true, let alone that it is necessary or a priori.

More recently, nativism has been reanimated by Chomsky's claims that children must have innate language-specific information that mediates acquisition of their native tongue. He argues that, given standard empiricist learning procedures, the linguistic data available to a child underdetermines the grammar on which they converge at a very young age, with relatively little effort or instruction.

The successes in linguistics have led to fruitful research on nativism in other domains of human knowledge: for example, arithmetic, the nature of physical objects, features of persons, and possession of concepts generally.

NATURAL DEDUCTION, TABLEAU AND SEQUENT SYSTEMS

Different presentations of the principles of logic reflect different approaches to the subject itself. The three kinds of system discussed here treat as

fundamental not logical truth, but consequence, the relation holding between the premises and conclusion of a valid argument. They are, however, inspired by different conceptions of this relation. Natural deduction rules are intended to formalize the way in which mathematicians actually reason in their proofs. Tableau systems reflect the semantic conception of consequence; their rules may be interpreted as the systematic search for a counter-example to an argument. Finally, sequent calculi were developed for the sake of their metamathematical properties.

All three systems employ rules rather than axioms. Each logical constant is governed by a pair of rules which do not involve the other constants and are, in some sense, inverse. Take the implication operator '$\rightarrow$', for example. In natural deduction, there is an introduction rule for '$\rightarrow$' which gives a sufficient condition for inferring an implication, and an elimination rule which gives the strongest conclusion that can be inferred from a premise having the form of an implication. Tableau systems contain a rule which gives a sufficient condition for an implication to be true, and another which gives a sufficient condition for it to be false. A sequent is an array $\Gamma \vdash \Delta$, where Γ and Δ are lists (or sets) of formulas. Sequent calculi have rules for introducing implication on the left of the '$\vdash$' symbol and on the right.

The construction of derivations or tableaus in these systems is often more concise and intuitive than in an axiomatic one, and versions of all three have found their way into introductory logic texts. Furthermore, every natural deduction or sequent derivation can be made more direct by transforming it into a 'normal form'. In the case of the sequent calculus, this result is known as the cut-elimination theorem. It has been applied extensively in metamathematics, most famously to obtain consistency proofs. The semantic inspiration for the rules of tableau construction suggests a very perspicuous proof of classical completeness, one which can also be adapted to the sequent calculus. The introduction and elimination rules of natural deduction are intuitionistically valid and have suggested an alternative semantics based on a conception of meaning as use. The idea is that the meaning of each logical constant is exhausted by its inferential behaviour and can therefore be characterized by its introduction and elimination rules.

Although the discussion below focuses on intuitionistic and classical first-order logic, various other logics have also been formulated as sequent, natural deduction and even tableau systems: modal logics, for example, relevance logic, infinitary and higher-order logics. There is a gain in understanding the role of the logical constants which comes from formulating introduction and elimination (or left and right) rules for them. Some authors have even suggested that one must be able to do so for an operator to count as logical.

A.M. UNGAR

NATURAL KINDS

Objects belonging to a natural kind form a group of objects which have some theoretically important property in common. For example, rabbits form a natural kind, all samples of gold form another, and so on. Natural kinds are contrasted with arbitrary groups of objects such as the contents of dustbins, or collections of jewels. The latter have no theoretically important property in common: they have no unifying feature. Natural kinds provide a system for classifying objects. Scientists can then use this system to predict and explain the behaviour of those objects. For these reasons, the topic of natural kinds is of special interest to metaphysics and to the philosophy of science.

NATURAL LAW

When made within the discourse of ethics, political theory, or legal theory or philosophy of law, the claim that there is a natural law is an offer to explain and defend certain claims often made, in different terms, in the discourse of moral argument, politics or law. In pre-theoretical moral discourse, certain choices, actions or dispositions may be asserted to be 'inhuman', 'unnaturally cruel', 'perverse' or 'morally unreasonable'. In pre-theoretical political discourse, certain proposals, policies or conduct may be described as violations of 'human rights'. In international law and jurisprudence, certain actions may be described as 'crimes against humanity' and citizens may claim immunity from legal liability or obligations by appealing to a 'higher law'. A natural law theory offers to explain why claims of this sort can be rationally warranted and true. It offers to do so by locating such claims in the context of a general theory of good and evil in human life so far as human life is shaped by deliberation and choice. Such a general theory can also be called a general theory of right and wrong in human choices and actions. It will contain both (1) normative propositions identifying types of choice, action or disposition as right or wrong, permissible, obligatory and so on, and (2) non-normative propositions about the objectivity and epistemological warrant of the normative propositions.

NATURAL THEOLOGY

Natural theology aims at establishing truths or acquiring knowledge about God (or divine matters generally) using only our natural cognitive resources. The phrase 'our natural cognitive resources' identifies both the methods and data for natural theology: it relies on standard techniques of reasoning and facts or truths in principle available to all human beings just in virtue of their possessing reason and sense perception. As traditionally conceived, natural theology begins by establishing the existence of God, and then proceeds by establishing truths about God's nature (for example, that God is eternal, immutable and omniscient) and about God's relation to the world.

A precise characterization of natural theology depends on further specification of its methods and data. One strict conception of natural theology – the traditional conception sometimes associated with Thomas Aquinas – allows only certain kinds of deductive argument, the starting points of which are propositions that are either self-evident or evident to sense perception. A broader conception might allow not just deductive but also inductive inference and admit as starting points propositions that fall short of being wholly evident.

Natural theology contrasts with investigations into divine matters that rely at least in part on data not naturally available to us as human beings. This sort of enterprise might be characterized as *revelation-based* theology, in so far as the supernatural element on which it relies is something supernaturally revealed to us by God. Revelation-based theology can make use of what is ascertainable by us only because of special divine aid. Dogmatic and biblical theology would be enterprises of this sort.

Critics of natural theology fall generally into three groups. The first group, the majority, argue that some or all of the particular arguments of natural theology are, as a matter of fact, unsuccessful. Critics in the second group argue that, in principle, natural theology cannot succeed, either because of essential limitations on human knowledge that make it impossible for us to attain knowledge of God or because religious language is such as to make an investigation into its truth inappropriate. The third group of critics holds that natural theology is in some way irrelevant or inimical to true religion. They argue in various ways that the objectifying, abstract and impersonal methods of natural theology cannot capture what is fundamentally important about the divine and our relation to it.

SCOTT MACDONALD

NATURALISM IN ETHICS

Ethical naturalism is the project of fitting an account of ethics into a naturalistic worldview. It includes nihilistic theories, which see no place for real values and no successful role for ethical thought in a purely natural world. The term 'naturalism' is often used more narrowly, however, to refer to cognitivist naturalism, which holds that ethical facts are simply natural facts and that ethical thought succeeds in discovering them.

G.E. Moore, attacked cognitivist naturalism as mistaken in principle, for committing what he called the 'naturalistic fallacy'. He thought a simple test showed that ethical facts could not be natural facts (the 'fallacy' lay in believing they could be), and he took it to follow that ethical knowledge would have to rest on nonsensory intuition. Later writers have added other arguments for the same conclusions. Moore himself was in no sense a naturalist, since he thought that ethics could be given a 'non-natural' basis. Many who elaborated his criticisms of cognitivist naturalism, however, have done so on behalf of generic ethical naturalism, and so have defended either ethical nihilism or else some more modest constructive position, usually a version of noncognitivism. Noncognitivists concede to nihilists that nature contains no real values, but deny that it was ever the function of ethical thought to discover such things. They thus leave ethical thought room for success at some other task, such as providing the agent with direction for action.

Defenders of cognitivist naturalism deny that there is a 'naturalistic fallacy' or that ethical knowledge need rest on intuition; and they have accused Moore and his successors of relying on dubious assumptions in metaphysics, epistemology, the philosophy of language and the philosophy of mind. Thus many difficult philosophical issues have been implicated in the debate.

NICHOLAS L. STURGEON

NATURALISM IN SOCIAL SCIENCE

Naturalism is a term used in several ways. The more specific meanings of 'naturalism' in the philosophy of social sciences rest on the great popular authority

acquired by modern scientific methods and forms of explanation in the wake of the seventeenth-century scientific revolution. For many of the thinkers of the European Enlightenment and their nineteenth-century followers the success of science in uncovering the laws governing the natural world was used as an argument for the extension of its methods into the study of morality, society, government and human mental life. Not only would this bring the benefit of consensus in these contested areas, but also it would provide a sound basis for ameliorative social reform. Among the most influential advocates of naturalism, in this sense, was the early nineteenth-century French philosopher Auguste Comte.

The authority of the new mechanical science, even as an account of non-human nature, continued to be resisted by romantic philosophers. However, the more limited task of resisting the scientific 'invasion' of human self-understanding was taken up by the Neo-Kantian philosophers of the latter part of the nineteenth century, in Germany. Followers and associates of this tradition (such as Windelband, Rickert, Dilthey and others) insist that there is a radical gulf between scientific knowledge of nature, and the forms of understanding which are possible in the sphere of humanly created meanings and cultures. This view is argued for in several different ways. Sometimes a contrast is made between the regularities captured in laws of nature, on the one hand, and social rules, on the other. Sometimes human consciousness and self-understanding is opposed to the non-conscious 'behaviour' of nonhuman beings and objects, so that studying society is more like reading a book or having a conversation than it is like studying a chemical reaction.

NATURALISTIC FALLACY

See Moore, George Edward; Naturalism in ethics

NATURALIZED EPISTEMOLOGY

The term 'naturalized epistemology' was coined by W.V. Quine to refer to an approach to epistemology which he introduced in his 1969 essay 'Epistemology Naturalized'. Many of the moves that are distinctive of naturalized epistemology were made by David Hume, but Quine's essay fixes the sense of the term as it is used today.

Naturalized epistemology has critical as well as constructive thrusts. In a critical spirit, 'naturalists' (theorists who identify with the label 'naturalized epistemology') abandon several assumptions that are part of the tradition. They reject Descartes' vision of epistemology as the attempt to convert our beliefs into an edifice resting on a foundation about which we have complete certainty. Descartes is wrong to equate knowledge with certainty, and wrong to think that knowledge is available through a priori theorizing, through reasoning which makes no use of experience. Nor should epistemology continue as David Hume's attempt to rest knowledge on an introspective study of the mind's contents. Moreover, the global sceptic's claim that there is no way to justify all our views at once, should either be conceded or ignored.

On the constructive side, naturalists suggest that in investigating knowledge we rely on the apparatus, techniques and assumptions of natural science. Accordingly, naturalized epistemology will be a scientific (and hence neither indefeasible nor a priori) explanation of how it is that some beliefs come to be knowledge. Issues of scepticism will be addressed only when they come up in the course of a scientific investigation.

Quine's seminal essay lays out the core of naturalized epistemology, but subsequent naturalists disagree on the appropriate responses to several issues, among them the following: First, may theories be tested on the basis of (independently plausible) theory-neutral observation, or are observations simply more theory? Second, after being naturalized, does epistemology survive as an autonomous discipline? Quine argues that epistemology should become a subfield of natural science, presumably a part of psychology, so that there is no separate field left specifically to philosophers. But can all our questions about knowledge be answered by natural scientists? Third, the claim that epistemology explains how knowledge comes to be suggests that epistemology will merely describe the origins of beliefs we take to be known; but what is the relationship between such descriptive issues and normative issues such as that of how we ought to arrive at our views? Fourth, to what extent is the new approach to epistemology susceptible to sceptical concerns such as those that so plagued traditional epistemologists, and how effective a response can be made to those concerns?

STEVEN LUPER

NATURE, AESTHETIC APPRECIATION OF

In the Western world, aesthetic appreciation of nature and its philosophical investigation came to fruition in the eighteenth century. During that time, aestheticians made nature the ideal object of aesthetic experience and analysed that experience

in terms of disinterestedness, thereby laying the groundwork for understanding the appreciation of nature in terms of the sublime and the picturesque. This philosophical tradition reached its zenith with Kant, while popular aesthetic appreciation of nature continued primarily in terms of the picturesque.

In the late twentieth century, renewed interest in the aesthetics of nature has produced various positions designed to avoid assimilating appreciation of nature with traditional models for aesthetic appreciation of art. Three are especially noteworthy. The first holds that the appreciation of nature is not in fact aesthetic; the second rejects the traditional analysis of aesthetic experience as disinterested, arguing instead that the aesthetic appreciation of nature involves engagement with nature; the third attempts to maintain the traditional analysis, while distinguishing aesthetic appreciation of nature by dependence on scientific knowledge.

These positions have a number of ramifications. In freeing aesthetic appreciation of nature from artistic models, they pave the way for a general environmental aesthetics comparable to other areas of philosophy, such as environmental ethics. Moreover, the significance given to scientific knowledge in the third position both explains the aesthetic appreciation associated with environmentalism and provides aesthetic appreciation of nature with a degree of objectivity that may make aesthetic considerations more effectual in environmental assessment.

ALLEN CARLSON

NATURE AND CONVENTION

The nature–convention distinction opposes instinctual or 'spontaneous' modes of comportment (those which follow from 'human nature') to those which are socially instituted or culturally prescribed. Its philosophic interest resides in its use to justify or contest specific forms of human behaviour and social organization. Since the 'conventional' is opposed to the 'natural' as that which is in principle transformable, the adherents of a particular order in human affairs have standardly sought to prove its 'naturality', while its critics have sought to expose its merely 'conventional' status. Relatedly, 'conventions' may be associated with what is distinctive to 'human', as opposed to 'bestial' nature, or denounced for their role in repressing our more 'natural' impulses.

KATE SOPER

NATURE, PHILOSOPHY OF

See Naturphilosophie

NATURPHILOSOPHIE

Naturphilosophie refers to the philosophy of nature prevalent especially in German philosophy, science and literary movements from around 1790 to about 1830. It pleaded for an organic and dynamic worldview as an alternative to the atomist and mechanist outlook of modern science. Against the Cartesian dualism of matter and mind which had given way to the mechanist materialism of the French Encyclopedists, Spinoza's dual aspect theory of mind and matter as two modes of a single substance was favoured. The sources of this heterogeneous movement lie in the philosophy of German idealism as well as in late classicism and Romanticism. The leading figure, Schelling, assimilated and stimulated the major trends and ideas through his work.

After the death of Hegel (1831) and of Goethe (1832), *Naturphilosophie* quickly disappeared from the mainstream. Yet it survived in various different forms, especially as an undercurrent of German culture and science, until the twentieth century.

NECESSARY TRUTH AND CONVENTION

Necessary truths have always seemed problematic, particularly to empiricists and other naturalistically-minded philosophers. Our knowledge here is a priori – grounded in appeals to what we can imagine or conceive (or can prove on that basis) – which seems hard to reconcile with such truths being factual, short of appealing to some peculiar faculty of a priori intuition. And what mysterious extra feature do necessary truths possess which makes their falsity impossible? Conventionalism about necessity claims that necessary truths obtain by virtue of rules of language, such as that 'vixen' means the same as 'female fox'. Because such rules govern our descriptions of all cases – including counterfactual or imagined ones – they generate necessary truths ('All vixens are foxes'), and our a priori knowledge is just knowledge of word meaning. Opponents of conventionalism argue that conventions cannot ground necessary truths, particularly in logic, and have also challenged the notion of analyticity (truth by virtue of meaning). More recent claims that some necessary truths are a

posteriori have also fuelled opposition to conventionalism.

ALAN SIDELLE

NEGATIVE THEOLOGY

The term 'negative theology' refers to theologies which regard negative statements as primary in expressing our knowledge of God, contrasted with 'positive theologies' giving primary emphasis to positive statements. The distinction was developed within Muslim, Jewish and Christian theism. If the negative way (*via negativa*) is taken to its limits, two questions arise: first, whether one may speak of God equally well in impersonal as in personal terms (blurring the distinction between theism and, say, the philosophical Hinduism of Śaṅkara); and second, whether it leads ultimately to rejecting any ultimate being or subject at all (blurring the distinction between theism and, say, the atheism of Mahāyāna Buddhism). However, within their original theistic context, positive and negative statements about God are interdependent, the second indispensably qualifying the first, the negative statements taken alone useless.

Negative qualifications on positive statements attributing so-called 'perfections' to God – for example, existence, life, goodness, knowledge, love or active power ('strength') – are obviously necessary if God is unimaginable. If his presence is always of his whole being and life all at once, in each place in space and time, he must be non-spatial and non-temporal in being and nature, and clearly he must be unimaginable. However, his supposed 'simplicity' and 'infinity' imply that he is much more radically outside the reach of understanding or 'comprehension', imposing the negative way at a deeper level than mere unimaginability. This unimaginability and incomprehensibility are key to theistic accounts of prayer and the mystical life.

NEO-KANTIANISM

In contrast to earlier research, which chose to distinguish up to seven schools of thought within the field of Neo-Kantianism, more recent scholarship takes two basic movements as its starting point: the Marburg School and the Southwest German School, which are based respectively on systematically oriented works on Kant published during the 1870s and 1880s by Hermann Cohen and Wilhelm Windelband.

Cohen held that Kant's concern in all three Critiques was to reveal those a priori moments which above all give rise to the domains of scientific experience, morality and aesthetics. Windelband on the other hand held that Kant's achievement lay in the attempt to create a critical science of norms which, instead of giving a genetic explanation of the norms of logic, morality and aesthetics, aimed instead to elucidate their validity. In both approaches, an initial phase during which Kant's doctrines were appropriated subsequently developed into the production of systems. Thus Cohen published a 'System of Philosophy' during the early years of the twentieth century, which consisted of the *Logik der reinen Erkenntnis* (Logic of Pure Knowledge) (1902), the *Ethik des reinen Willens* (Ethics of Pure Will) (1904) and the *Ästhetik des reinen Gefühls* (Aesthetics of Pure Feeling) (1912) and which radicalized the operative approach of his work on Kant. Later, Cohen conceived a *Religion der Vernunft aus den Quellen des Judentums* (*Religion of Reason from the Sources of Judaism*) (1919). Windelband, on the other hand, who made a name for himself primarily in the sphere of the history of philosophy, understood philosophy to be essentially concerned with value, anchored in transcendental consciousness. He emphatically linked the classical division of philosophy into logic, ethics and aesthetics to the values of Truth, Goodness and Beauty and also tried to situate the philosophy of religion in this context.

Apart from Cohen, the Marburg School is represented by Paul Natorp and Ernst Cassirer, whose early works followed Cohen's philosophical views (compare Natorp's interpretation of the Platonic doctrine of ideas and Cassirer's history of the problem of knowledge), but whose later works modified his approach. Nevertheless, their extensions and developments can also be explained within the framework of the original Marburg doctrines. The ontological turn which Natorp undertook in his later years can be seen as a radicalization of Cohen's principle of origin, which Natorp believed could not be expressed in terms of pure intellectual positing, and the operative moment introduced by Cohen lives on as a theory of creative formation in Cassirer's theory of symbolic forms.

In addition to Windelband, the Southwest German school of Neo-Kantianism is represented by Heinrich Rickert, Emil Lask, Jonas Cohn and Bruno Bauch. Windelband instigated the systematic approach of the Southwest School, but it was left to Rickert to develop it fully. Unlike Windelband,

who traced the difference between history and science back to the difference between the idiographic and the nomothetic methods, Rickert distinguished between the individualizing concepts of history and the generalizing concepts of science. During his middle period he turned his attention to the problem of articulating a system of values. In his later works, Rickert also turned towards ontology, a development which should not necessarily be interpreted as a break with the constitutional theories of his early years. In concrete terms, building on his earlier theories concerning the constitutive role of concepts in experience, Rickert henceforth distinguishes not only the realm of scientific and cultural objects and the sphere of values, but also the further ontological domains of the world of the free subject and the metaphysical world, which is the object of faith and which can only be comprehended by thinking in symbols.

Lask's theoretical philosophy was characterized by a turn to objectivism. In contrast to the classical Neo-Kantian conception of knowledge, according to which everything given is determined by the forms of cognition, Lask sees matter as that element which determines meaning. Accordingly, at the centre of his theory of knowledge is not the subject's activity in constituting the object, but the subject's openness to the object. In the final stage of his philosophy, however, he once more attributed to the subject an autonomous role in the actualization of knowledge. Cohn contributed to Southwest German Neo-Kantianism not only his *Allgemeine Ästhetik* (General Theory of Aesthetics) (1901), but also works on the philosophy of culture and education as well as on the systematic articulation of values and the problem of reality. During the 1920s Cohn moved towards dialectics. In contrast to Hegel, however, he understood this to mean critical dialectics inasmuch as it does not aim to sublate or overcome opposition, but merely sets itself the unending task of attempting to resolve irreconcilable contradictions.

Finally, Bauch can be regarded as the most essentially synthetic thinker of the Southwest German Neo-Kantian school. He tried to demonstrate the inseparable connectedness of individual problems which had generally been treated separately. Apart from his great Kantian monographs, these ideas are also put forward in his systematic works on the questions of theoretical and practical philosophy, such as his study *Wahrheit, Wert und Wirklichkeit* (Truth, Value and Reality) (1923) and his *Grundzüge der Ethik* (Fundamentals of Ethics) (1935).

Despite the one-sidedness of its reception of Kant's doctrines, Neo-Kantianism was important for the momentum it gave to research into Kantian philosophy during the twentieth century. Its systematic achievement lies in its development of the normative concept of validity and its programmatic outline for a philosophy of culture.

HANS-LUDWIG OLLIG
Translated from the German
by JANE MICHAEL and NICHOLAS WALKER

NEOPLATONISM

Neoplatonism was the final flowering of ancient Greek thought, from the third to the sixth or seventh century AD. Building on eight centuries of unbroken philosophical debate, it addressed questions such as: What is the true self? What is consciousness and how does it relate to reality? Can intuition be reconciled with reason? What are the first causes of reality? How did the universe come into being? How can an efficient cause retain its identity and yet be distributed among its effects? Why does the soul become embodied? What is the good life?

There were several flavours of Neoplatonism, reflecting the concerns and backgrounds of its practitioners, who ranged from Plotinus and his circle of freelance thinkers to the heads of the university schools of the Roman Empire, Proclus, Ammonius and Damascius. In the later, more analysed form, we see a rich scheme of multilayered metaphysics, epistemology and ethics, but also literary theory, mathematics, physics and other subjects, all integrated in one curriculum. Neoplatonism was not just a philosophy but the higher education system of its age.

The Neoplatonism that came to dominate the ancient world from the fourth century was an inseparable mixture of inspired thought and scholastic order. To this may be traced some of its internal conceptual conflicts: for example, the free individual soul versus the ranks of being, personal experience versus demonstrative knowledge. To this may also be traced its appeal to polar audiences: mystics and mathematizing scientists, romantics and rationalists.

To the Neoplatonist, knowledge consists of degrees of completion. Take the example of tutor and student. Both study the same things, but the tutor has a wider and more intimate knowledge. The tutor opens the student's mind to the breadth and intricacies of the study-matter, and corrects the student's deliberations. So it is with the Neoplatonic levels of knowledge. Every level has access to the entire spectrum of what there is to know, but each with its appropriate adverbial modifier. At the 'lower' level an individual comprehends things 'particularly' and is concerned with the 'images'

or presentations of mind and sense-impressions of the qualities of physical things. At the 'higher' level, an individual apprehends things 'wholly', as universal statements (often called 'laws' and 'canons'). The concern is with propositions about what is true or false, self-grounded and logically necessary. Thus the higher level corrects and supplies the 'criterion' for the lower level.

Knowledge, however, is not an end in itself, but a means to salvation. Increasing awareness puts us in touch with the levels of reality of which we ourselves are part. The ultimate reality is none other than the fundamental unity out of which all came into being: God. In this union we recover our true good.

As the summation of ancient Greek philosophy, Neoplatonism was transmitted to Byzantium, Islam and western Europe. It was the prime intellectual force behind the protagonists of the Italian Renaissance, and its influence was felt until the nineteenth century.

NEUTRAL MONISM

Neutral monism is a theory of the relation of mind and matter. It holds that both are complex constructions out of more primitive elements that are 'neutral' in the sense that they are neither mental nor material. Mind and matter, therefore, do not differ in the intrinsic nature of their constituents but in the manner in which the constituents are organized. The theory is monist only in claiming that all the basic elements of the world are of the same fundamental type (in contrast to mind–body dualism); it is, however, pluralist in that it admits a plurality of such elements (in contrast to metaphysical monism).

NICHOLAS GRIFFIN

NEUTRALITY, POLITICAL

The principle of political neutrality, which requires the state to remain neutral on disputed questions about the good, is an extension of traditional liberal principles of toleration and religious disestablishment. However, since neutrality is itself a contested concept, the principle remains indeterminate: is it, for example, a requirement of neutral reasons for legislation (or neutral legislative intentions) or is it a more exacting requirement of equal impact in so far as legislative consequences are concerned? The answer must surely reflect the deeper values that are used to justify the neutrality principle. This raises further problems, however. If the principle is based upon certain value commitments – such as the importance of equality or individual autonomy – then it cannot require us to be neutral about all values. It requires some sort of distinction between principles of right (of which neutrality is one) and conceptions of the good (among which neutrality is required). Critics believe that liberal principles of right are symptomatic of a deeper liberal bias in favour of individuality as a way of life. Perhaps liberals should embrace this point, and accept that the neutrality they advocate is quite superficial compared to the depth of their own value commitments.

JEREMY WALDRON

NEWTON, ISAAC (1642–1727)

Newton is best known for having invented the calculus and formulated the theory of universal gravity – the latter in his *Principia*, the single most important work in the transformation of natural philosophy into modern physical science. Yet he also made major discoveries in optics, and put no less effort into alchemy and theology than into mathematics and physics.

Throughout his career, Newton maintained a sharp distinction between conjectural hypotheses and experimentally established results. This distinction was central to his claim that the method by which conclusions about forces were inferred from phenomena in the *Principia* made it 'possible to argue more securely concerning the physical species, physical causes, and physical proportions of these forces'. The law of universal gravity that he argued for in this way nevertheless provoked strong opposition, especially from such leading figures on the Continent as Huygens and Leibniz: they protested that Newton was invoking an occult power of action-at-a-distance insofar as he was offering no contact mechanism by means of which forces of gravity could act. This opposition led him to a tighter, more emphatic presentation of his methodology in the second edition of the *Principia*, published twenty-six years after the first. The opposition to the theory of gravity faded during the fifty to seventy-five years after his death as it fulfilled its promise on such issues as the non-spherical shape of the earth, the precession of the

equinoxes, comet trajectories (including the return of 'Halley's Comet' in 1758), the vagaries of lunar motion and other deviations from Keplerian motion. During this period the point mass mechanics of the *Principia* was extended to rigid bodies and fluids by such figures as Euler, forming what we know as 'Newtonian' mechanics.

WILLIAM L. HARPER
GEORGE E. SMITH

NICHOLAS OF CUSA (1401–64)

Also called Nicolaus Cusanus, this German cardinal takes his distinguishing name from the city of his birth, Kues (or Cusa, in Latin), on the Moselle river between Koblenz and Trier. Nicholas was influenced by Albert the Great, Thomas Aquinas, Bonaventure, Ramon Llull, Ricoldo of Montecroce, Master Eckhart, Jean Gerson and Heimericus de Campo, as well as by more distant figures such as Plato, Aristotle, Proclus, Pseudo-Dionysius and John Scottus Eriugena. His eclectic system of thought pointed in the direction of a transition between the Middle Ages and the Renaissance. In his own day as in ours, Nicholas was most widely known for his early work *De docta ignorantia* (On Learned Ignorance). In it, he gives expression to his view that the human mind needs to discover its necessary ignorance of what the Divine Being is like, an ignorance that results from the infinite ontological and cognitive disproportion between Infinity itself (that is, God) and the finite human or angelic knower. Correlated with the doctrine of *docta ignorantia* is that of *coincidentia oppositorum in deo*, the coincidence of opposites in God. All things coincide in God in the sense that God, as undifferentiated being, is beyond all opposition, beyond all determination as *this* rather than *that*.

Nicholas is also known for his rudimentary cosmological speculation, his prefiguring of certain metaphysical and epistemological themes found later in Leibniz, Kant and Hegel, his ecclesiological teachings regarding the controversy over papal versus conciliar authority, his advocacy of a religious ecumenism of sorts, his interest in purely mathematical topics and his influence on the theologian Paul Tillich in the twentieth century. A striking tribute to Nicholas' memory still stands today: the hospice for elderly, indigent men that he caused to be erected at Kues between 1452 and 1458 and that he both endowed financially and invested with his personal library. This small but splendid library, unravaged by the intervening wars and consisting of some three hundred volumes, includes manuscripts written in Nicholas' own hand.

NIETZSCHE, FRIEDRICH (1844–1900)

Introduction

Appointed professor of classical philology at the University of Basel when he was just 24 years old, Nietzsche was expected to secure his reputation as a brilliant young scholar with his first book, *Die Geburt der Tragödie* (*The Birth of Tragedy*) (1872). But that book did not look much like a work of classical scholarship. Bereft of footnotes and highly critical of Socrates and modern scholarship, it spoke in rhapsodic tones of ancient orgiastic Dionysian festivals and the rebirth of Dionysian tragedy in the modern world. Classical scholars, whose craft and temperament it had scorned, greeted the book with scathing criticism and hostility; even Nietzsche eventually recognized it as badly written and confused. Yet it remains one of the three most important philosophical treatments of tragedy (along with those of Aristotle and Hegel) and is the soil out of which Nietzsche's later philosophy grew. By 1889, when he suffered a mental and physical collapse that brought his productive life to an end, Nietzsche had produced a series of thirteen books which have left a deep imprint on most areas of Western intellectual and cultural life, establishing him as one of Germany's greatest prose stylists and one of its most important, if controversial, philosophers.

Nietzsche appears to attack almost everything that has been considered sacred: not only Socrates and scholarship, but also God, truth, morality, equality, democracy and most other modern values. He gives a large role to the will to power and he proposes to replace the values he attacks with new values and a new ideal of the human person (the *Übermensch* meaning 'overhuman' or 'superhuman'). Although Nazi theoreticians attempted to associate these ideas with their own cause, responsible interpreters agree that Nietzsche despised and unambiguously rejected both German nationalism and anti-Semitism. Little else in his thought is so unambiguous, at least in part because he rarely

writes in a straightforward, argumentative style, and because his thought changed radically over the course of his productive life. The latter is especially true of his early criticism of Socrates, science and truth.

Nietzsche's philosophizing began from a deep sense of dissatisfaction with modern Western culture, which he found superficial and empty in comparison with that of the ancient Greeks. Locating the source of the problem in the fact that modern culture gives priority to science (understood broadly as including all forms of scholarship and theory), whereas Presocratic Greece had given priority to art and myth, he rested his hopes for modern culture on a return to the Greek valuation of art, calling for a recognition of art as 'the highest task and the truly metaphysical activity of this life'.

He soon turned his back on this early critique of science. In the works of his middle period he rejects metaphysical truth but celebrates the valuing of science and empirical truth over myth as a sign of high culture. Although he had earlier considered it destructive of culture, he now committed his own philosophy to a thoroughgoing naturalistic understanding of human beings. He continued to believe that naturalism undermines commitment to values because it destroys myths and illusions, but he now hoped that knowledge would purify human desire and allow human beings to live without preferring or evaluating. In the works of his final period, Nietzsche rejects this aspiration as nihilistic.

In his final period, he combined a commitment to science with a commitment to values by recognizing that naturalism does not undermine all values, but only those endorsed by the major ideal of value we have had so far, the ascetic ideal. This ideal takes the highest human life to be one of self-denial, denial of the natural self, thereby treating natural or earthly existence as devoid of intrinsic value. Nietzsche saw this life-devaluing ideal at work in most Western (and Eastern) religion and philosophy. Values always come into existence in support of some form of life, but they gain the support of ascetic religions and philosophies only if they are given a life-devaluing interpretation. Ascetic priests interpret acts as wrong or 'sinful' because the acts are selfish or 'animal' – because they affirm natural instincts – and ascetic philosophers interpret whatever they value – truth, knowledge, philosophy, virtue – in non-natural terms because they share the assumption that anything truly valuable must have a source outside the world of nature, the world accessible to empirical investigation. Only because Nietzsche still accepted this assumption of the ascetic ideal did naturalism seem to undermine all values.

According to his later thought, the ascetic ideal itself undermines values. First it deprives nature of value by placing the source of value outside nature. Then, by promoting the value of truth above all else, it leads to a denial that there is anything besides nature. Among the casualties of this process are morality and belief in God, as Nietzsche indicated by proclaiming that 'God is dead' and that morality will gradually perish. Morality is not the only possible form of ethical life, however, but a particular form that has been brought about by the ascetic ideal. That ideal has little life left in it, according to Nietzsche, as does the form of ethical life it brought about. Morality now has little power to inspire human beings to virtue or anything else. There is no longer anything to play the essential role played by the ascetic ideal: to inspire human beings to take on the task of becoming more than they are, thereby inducing them to internalize their will to power against themselves. Modern culture therefore has insufficient defences against eruptions of barbarism, which Nietzsche predicted as a large part of the history of the twentieth and twenty-first centuries.

But Nietzsche now saw that there was no way to go back to earlier values. His hope rested instead with 'new philosophers' who have lived and thought the values of the ascetic ideal through to their end and thereby recognized the need for new values. His own writings are meant to exhibit a new ideal, often by exemplifying old virtues that are given a new, life-affirming interpretation.

1 Life

Nietzsche was born in Rocken, a small village in the Prussian province of Saxony, on 15 October 1844. His father, a Lutheran minister, became seriously ill in 1848 and died in July 1849 of what was diagnosed as 'softening of the brain'. His brother died the following year, and Nietzsche's mother moved with her son and daughter to Naumberg, a town of 15,000 people, where they lived with his father's mother and her two sisters. In

1858, Nietzsche was offered free admission to Pforta, the most famous school in Germany. After graduating in 1864 with a thesis in Latin on the Greek poet Theogonis, he registered at the University of Bonn as a theology student. The following year he transferred to Leipzig where he registered as a philology student and worked under the classical philologist Friedrich Ritschl. The events of his Leipzig years which had the most profound and lasting influence on his later work were his discoveries of Schopenhauer's *Die Welt als Wille und Vorstellung* (*The World as Will and Representation*) and F.A. Lange's *Geschichte des Materialismus* (*History of Materialism*), and the beginning of a personal relationship with Richard Wagner (see SCHOPENHAUER, A.; LANGE, F.A.). Nietzsche became Ritschl's star pupil, and on Ritschl's recommendation he was appointed to the Chair of Classical Philology at Basel in 1869 at the age of twenty-four. Leipzig proceeded to confer the doctorate without requiring a dissertation.

Basel's proximity to the Wagner residence at Tribschen allowed Nietzsche to develop a close relationship with Richard and Cosima Wagner. Sharing with the composer a deep love of Schopenhauer and a hope for the revitalization of European culture, he initially idealized Wagner and his music. His first book, *Die Geburt der Tragödie* (*The Birth of Tragedy*) (1872), used Schopenhauer's philosophy to interpret Greek tragedy and to suggest that Wagner's opera constituted its rebirth and thereby the salvation of modern culture. Torn between philology and philosophy since shortly after his discovery of Schopenhauer, Nietzsche devoted much of his teaching to the texts of ancient Greek and Roman philosophy and hoped that his first book would establish his credentials as a philosopher. Instead, its unorthodox mixture of philosophy and philology merely served to damage his reputation as a philologist.

In 1879, he resigned his chair at Basel because of health problems that had plagued him for years. In the meantime, he had become progressively estranged from Wagner, a process that culminated in the 1878 publication of the first volume of *Menschliches, Allzumenschliches* (*Human, All Too Human*), a positivist manifesto that praised science rather than art as indicative of high culture. The ten productive years left to him after his retirement were marked by terrible health problems and a near absence of human companionship. Living alone in Italian and Swiss boarding houses, he wrote ten books, each of which has at least some claim to being a masterpiece. His last seven books mark a high point of German prose style.

In January 1889, Nietzsche collapsed in Turin. He wrote a few lucid and beautiful (although insane) letters during the next few days, and after that nothing of which we can make any sense. Following a brief institutionalization, he lived with his mother and then his sister until his death in Weimar on 25 August 1900.

2 Writings and development

During the sixteen years between his first book and his last productive year, Nietzsche's thinking underwent remarkable development, usually with little notification to his readers. The traditional grouping of his writings into three major periods is followed here, although there is significant development within each period. In addition to *The Birth of Tragedy* his early work consists of four essays of cultural criticism – on David Strauss, history, Schopenhauer, and Wagner – published separately but linked together as *Unzeitgemäße Betrachtungen* (*Unfashionable Observations*) (1873–6), plus a number of largely finished essays and fragments that belong to the *Nachlaß* of the period. The most important of the essays are 'Über Wahrheit und Lüge im außermoralischen Sinne' ('On Truth and Lies in a Nonmoral Sense'), 'Homer's Wettkampf' ('Homer's Contest'), and 'Die Philosophie im tragischen Zeitalter der Griechen' ('Philosophy in the Tragic Age of the Greeks').

These early writings sound a note of great dissatisfaction with European (Enlightenment) culture, of which Socrates is taken as the earliest representative and continuing inspiration. At the base of Socratic culture Nietzsche finds the belief that life's highest goal is the theoretical grasp of truth at which science and philosophy aim. Theory's claim to provide truth has been undermined, he thinks, by the doctrine of Kant and Schopenhauer that discursive thought gives access not to things-in-themselves but only to 'appearance' (see KANT, I. §5; SCHOPENHAUER, A.). Nietzsche's suggestion for saving European culture is that art should replace theory as the most valued, the 'truly metaphysical', human activity. At first, his main argument for elevating art is that it is more truthful than theory. But he also suggests a very different argument: that theory is destructive of culture unless it is guided and limited by the needs of life which art serves. In his essay on history, the second argument has largely replaced the first. He argues that when practised as autonomous theory, devoted solely to truth, history destroys the limited and mythical horizons required by life and action. And if we emphasize for another generation the naturalistic understanding of human beings at which Socratic culture has now arrived (for example, the denial of a cardinal distinction between humans and other animals), we will only further our culture's disintegration into

chaotic systems of individual and group egoism. Nietzsche suggests that history can be harnessed to serve the needs of life, for instance when it is written to emphasize great lives and other aspects that encourage individuals to set lofty and noble goals for themselves. Such history is as much art as it is theory or science.

Nietzsche turns decisively away from such criticism of pure theory in the writings of his middle period, *Human, All Too Human* (1878–80) and *Morgenröte* (*Daybreak*) (1881). He here celebrates as a sign of high culture an appreciation of the little truths won by rigorous method, and presents his own philosophy as a form of natural science that serves only truth. He also commits himself to the truth of the naturalism he earlier considered so dangerous: there is no cardinal distinction between humans and other animals; everything about human beings, including their values, can be explained as a development from characteristics found among other animals. At the beginning of this period Nietzsche struggles with how naturalism can be compatible with a commitment to values, for he sees it as exposing and thereby undermining the illusions that are needed in order to find value in life. In *Human*, his hope is that knowledge will gradually purify 'the old motives of violent desire' until one can live 'as in *nature*', without preferring or evaluating, but 'gazing contentedly, as though at a spectacle' (*Human* §34). Nietzsche later has Zarathustra mock this spectator conception of knowledge and life as 'immaculate perception' (*Zarathustra* II: §15).

Nietzsche's final period begins with *Die Fröhliche Wissenschaft* (*The Gay Science*) (1882), which replaces the spectator conception with one in which the 'knower' belongs to the dance of existence and is one of its 'masters of ceremony' (*The Gay Science* §54). This formulation expresses his new confidence that naturalism, which he often calls 'knowledge', is compatible with commitment to values. In this period, Nietzsche once again celebrates art, criticizes Socrates and denies the autonomy of theory, suggesting to some that he has reverted to the viewpoint of his early period. Evidence is provided throughout this entry for an alternative interpretation: the later Nietzsche does not deny that theory can provide truth, and he remains as committed to the pursuit of truth as he was in his middle period. The difference is that he now recognizes in even the apparently autonomous theory of his middle period a commitment to an ideal that is external to and served by theory, namely, the ascetic ideal. Nietzsche returns to the suggestion of his first book, that theory is not autonomous; however, he now objects not to theory, but only to the ideal that theory has served (see §§6 and 7 of this entry). The works of Nietzsche's final period are largely devoted to uncovering, criticizing and offering an alternative to that ideal.

Gay Science was followed by *Also Sprach Zarathustra* (*Thus Spoke Zarathustra*) (1883–5), a fictional tale used as a vehicle for Nietzsche's most puzzling and infamous doctrines, including the overhuman (*Übermensch*), will to power and eternal recurrence. He considered this to be the deepest work in the German language and suggested that chairs of philosophy might one day be devoted to its interpretation. Our surest guides to it at present are the other books of his final period, especially the two that followed it: *Jenseits von Gut und Böse* (*Beyond Good and Evil*) (1886) and *Zur Genealogie der Moral* (*On the Genealogy of Morality*) (1887). These masterpieces show Nietzsche at the height of his powers as a thinker, an organizer and an artist of ideas. Yet some prefer his last five books. At the beginning of 1888, Nietzsche published *Der Fall Wagner* (*The Case of Wagner*) and then composed four short books before the year was out: *Die Götzen-Dämmerung* (*The Twilight of the Idols*), an obvious play on Wagner's *Götterdämmerung* (*Twilight of the Gods*), puts the finishing touches to his accounts of knowledge and philosophy and offers his final critique of Socrates; *Der Antichrist* (*The Antichrist*), a critique of Pauline Christianity, offers a relatively sympathetic portrait of Jesus; and *Ecce Homo*, Nietzsche's own portrait of his life and work under such chapter headings as 'Why I write such good books'. It is easy to hear signs of his impending insanity in the shrill tone and self-promotion that sometimes takes over in these books (although not in the very funny and brilliantly anti-Socratic chapter headings of *Ecce Homo*), and perhaps also in the fall-off in organizational and artistic power from the masterpieces of the previous two years. *Nietzsche Contra Wagner*, which he dated Christmas 1888, leaves a different impression. Nietzsche's shortest and perhaps most beautiful book, it is a compilation of passages from earlier works, with a few small improvements, as if aiming at perfection. He collapsed nine days later.

3 *The* Nachlaß

Nietzsche left behind a large body of unpublished material, his *Nachlaß*, which technically should include *The Antichrist* and *Ecce Homo*, published by his sister in 1895 and 1908 respectively. However, Nietzsche had made arrangements for their publication and prepared a printer's copy of each. For purposes of understanding his philosophy, these are therefore accorded the same status as his earlier works and are not usually considered to be part of his *Nachlaß*. This entry gives a very secondary role

to the remainder of Nietzsche's *Nachlaß*, which includes the relatively polished essays written in the early 1870s (mentioned in §2 of this entry). These essays are informative about Nietzsche's early views, and are sometimes also thought to provide a clearer statement of his later views of truth and language than do the works he published. The interpretation of Nietzsche's development offered here supports a very different view: that Nietzsche chose not to publish these essays because he soon progressed beyond them to quite opposed views.

Another issue that divides interpreters concerns the weight to give to the notes of Nietzsche's later years. Many treat them as material he would have published if he had remained productive for longer. But since he might instead have rejected and disposed of much of this material, others advise great caution in its use. Further, we often cannot determine the use Nietzsche had in mind for particular notes even when he wrote them. Nietzsche *composed* his books to lead prepared readers to certain views. The rich context and clues for reading supplied by his books, when they are attended to, provide a check on interpretive licence and a basis for getting at Nietzsche's own thinking that has no parallel in the case of the *Nachlaß* material. This applies to the entire contents of *Der Wille zur Macht* (*The Will to Power*), which some have regarded as Nietzsche's magnum opus. Although he did announce it as 'in preparation', there is evidence that he dropped his plans to publish a work of this title; the book we have is actually a compilation of notes from the years 1883–8 selected from his notebooks and arranged in their present form by his sister and editors appointed by her. Such notes may sometimes help in understanding what Nietzsche actually did publish. But it is difficult to justify giving them priority when they suggest views that differ from and are even contrary to those suggested by a careful reading of Nietzsche's books (see §§11–12 of this entry).

4 Truth and metaphysics

In the writings of his early and middle periods, Nietzsche often appears to deny that any of our theories and beliefs are really true. By the end of his final period, he denies only metaphysical truth. The rejection of metaphysics forms the cornerstone of his later philosophy.

What Nietzsche rejects as metaphysics is first and foremost a belief in a second world, a metaphysical or true world. *Human, All Too Human* offers a genealogy of this belief. Receiving their first idea of a second world from dreams, human beings originally share with 'everything organic' a belief in the existence of permanent things (substance) and free will. When reflection dawns and they fail to find evidence of these in the world accessible to empirical methods, they conclude that these methods are faulty, and that the real world is accessible only to non-empirical methods. They thus take the empirical world to be a mere appearance or distortion of a second world, which is thereby constituted as the true one. Metaphysics is purported knowledge of this non-empirical world. *The Birth of Tragedy* affirms metaphysics in this sense – 'an artists' metaphysics' he later called it – in the suggestion that perception and science confine us to mere appearance, whereas truth is accessible in the special kind of preconceptual experience characteristic of Dionysian art.

Human, All Too Human sets out to undermine metaphysics by showing that knowledge of a non-empirical world is cognitively superfluous. Nietzsche's Enlightenment predecessors had already established the adequacy of empirical methods to explain what goes on in the nonhuman world. However, belief in a metaphysical world persisted because that world is assumed to be necessary to account for the things of the highest value in the human world. Nietzsche sought to explain the origin of this assumption and to undermine it. The assumption was made, he claims, because thinkers were unable to see how things could originate from their opposites: disinterested contemplation from lust, living for others from egoism, rationality from irrationality. They could deny this origination only by positing for 'the more highly valued thing a miraculous source in the very kernel and being of the "thing-in-itself"'. Nietzsche offers a naturalistic account of higher things, which presents them as sublimations of despised things and therefore as 'human, all too human'. Once it is clear that we can explain their origin without positing a metaphysical world, he expects the interest in such a world to die out. We cannot deny the bare possibility of its existence, however, because 'we view all things through the human head and cannot cut this head off; yet the question remains what of the world would still be there if we had cut it off' (*Human* §§1, 9).

Nietzsche later goes a step further and denies the very existence of a metaphysical world. His history of the 'true' world in *Twilight of the Idols* offers a six-stage sketch of how the metaphysical world came to be recognized as a 'fable'. Stage Four corresponds to the position of *Human*: the 'true' world is cognitively superfluous. In Stage Five, its existence is denied. Stage Six adds that without a true world, there is no merely apparent world either: the empirical world originally picked out as 'merely apparent' is the only world there is. Nietzsche thus makes clear that he has moved beyond the

assumption that there *might* be a metaphysical world to a positing of the empirical world as the only one. He dismisses the whole idea of a second world as unintelligible. The books after *Beyond Good and Evil* proceed on this assumption: they no longer claim that the empirical world is a mere appearance or, what amounts to the same thing, that empirical truths are illusions or falsifications.

5 Knowledge

The position on knowledge to which Nietzsche is led by his rejection of metaphysics is a combination of empiricism, antipositivism and perspectivism. Claiming in his later works that 'all evidence of truth comes only from the senses', and that we have science 'only to the extent that we have decided to *accept* the testimony of the senses – to the extent to which we sharpen them further, arm them, and think them through', he considers the rest of purported knowledge 'miscarriage and not yet science', or formal science, like pure logic and mathematics (*Beyond Good and Evil* §134; *Twilight* III §3). The latter, he now insists, departing from his earlier stand that they falsify reality, make no claim about reality at all. Nietzsche's empiricism amounts to a rejection of any wholesale disparaging of sense experience, an insistence that the only bases for criticizing or correcting particular deliverances of the senses are other sense experiences or theories based on them.

Nietzsche's antipositivism involves a rejection of two aspects associated with some other versions of empiricism. First, he rejects foundationalism. Anticipating many later critics of positivism, he denies that there is any experience that is unmediated by concepts, interpretation or theory. Sense experience, our only evidence of truth, is always already interpreted, and knowledge is therefore interpretation, as opposed to the apprehension of unmediated facts. Nietzsche also avoids the problem of needing an a priori theory to establish his empiricism, which he bases instead on his genealogy of the belief in a metaphysical world (a genealogy that is itself empirical in that it accepts the testimony of the senses) and a diagnosis and working-through of the intellectual confusions that have locked previous philosophers into that belief. Clearing away these confusions (especially pictures of knowledge that set the world's true nature over against its appearances) removes all intellectual basis for considering sense experience in principle problematic, and all intellectual motivation for pursuing a priori knowledge. Philosophers may, however, still have non-intellectual motives for this pursuit (see §6 of this entry). The upshot of Nietzsche's antipositivism is that what counts as knowledge is always revisable in the light of new or improved experience. This reinforces his empiricism, and in no way devalues empirical theories or denies that they can give us truth.

Nietzsche's perspectivism is often thought to imply that empirical knowledge offers us 'only a perspective' and not truth. But is perspectivism itself only a perspective? If not, it is false; if so, it is not clear why we should accept perspectivism rather than some other perspective. And Nietzsche himself puts forward as truths not only perspectivism, but also many other claims.

We can avoid saddling Nietzsche with these problems by recognizing that, at least in its mature and most important formulation (at *Geneology* III §12), perspectivism is a claim about knowledge; it is not a claim about truth, and it does not entail that truth is relative to perspective. Further, 'perspectives' are constituted by affects, not beliefs. The point is *not* that knowledge is always from the viewpoint of a particular set of beliefs and that there are always alternative sets that would ground equally good views of an object (see RELATIVISM). Such a view inevitably saddles perspectivism with relativism and problems of self-reference. Nietzsche's explicit point in describing knowledge as perspectival is to guard against conceiving of knowledge as 'disinterested contemplation'.

His early essay 'Truth and Lie' did use the impossibility of disinterested knowledge to devalue empirical knowledge, arguing that the latter was only a perspective and an illusion. But the point of the *Genealogy*'s claim that there is 'only a perspective knowing' is quite the reverse: to guard against using the idea of 'pure' knowing to devalue the kind of knowledge we have. The metaphor of perspective sets up disinterested knowing as the equivalent of the recognizably absurd notion of seeing something from nowhere. If the conception of knowledge ruled out by perspectivism really is absurd, however – and Nietzsche insists that it is – then it excludes only a kind of knowledge of which we can make no sense and which we could not really want. This explains why so many find perspectivism obvious and even self-evident; but so interpreted, it does nothing to devalue empirical knowledge.

Why does Nietzsche deny the possibility of disinterested knowledge? That surely does not follow from the impossibility of seeing something from nowhere. His early basis for this denial was Schopenhauer's doctrine that the intellect originates as servant to the will, but he accepted the same doctrine in later works on the basis of a thoroughgoing Darwinian naturalism. Human cognitive capacities exist because of the evolutionary advantage they confer on the species, and no such advantage is to be found in attending to any and all

features of reality. The intellect must be directed to certain features – initially at least, those most relevant to human survival and reproduction. Affect – emotion, feeling, passion, value orientations – turns the mind in a particular direction, focusing its attention on certain features of reality and pushing it to register them as important; knowledge is only acquired when the intellect is so pushed and focused. Nietzsche's perspectivism is a metaphorical formulation of this naturalistic understanding of knowledge.

Because knowledge is always acquired from the viewpoint of particular interests and values, there are therefore always other affective sets that would focus attention on different aspects of reality. Nietzsche's use of the metaphor of perspective thus implies that knowledge is limited in the sense that there are always other things to know, but not that perspectives block our access to truth. Affects are our access, the basis of all access to truth. If its perspectival character raises any problems for knowledge, it is only because being locked into a particular perspective can make one unable to appreciate features of reality that are apparent from other perspectives. Nietzsche's solution is simple: the more affects we know how to bring to bear on a matter, the more complete our knowledge of it will be.

This does not mean that true knowledge requires assuming as many perspectives as possible. Knowledge does not require complete knowledge, and complete knowledge is not Nietzsche's epistemological ideal. In fact, he suggests that the greatest scholars tend to serve knowledge by immersing themselves deeply and thoroughly in some particular perspective, so much so that they damage themselves as human beings. The situation is different for philosophers because their ultimate responsibility is not knowledge, but values. To undertake the task to which Nietzsche assigns them, they need practice in shifting perspectives. This explains much that is distinctive about his way of writing philosophy: why it involves so much affect and seems so given to extremes of expression. He uses different affective stances – assuming them for a while – in order to show us features of reality that are visible from them. More importantly, by moving from one perspective to another, he attempts to show philosophers the kind of 'objectivity' that is required for their task: objectivity understood not as disinterested contemplation, but as a matter of not being *locked into* any particular valuational perspective, as an ability to move from one affective set to another.

6 Philosophy and the ascetic ideal

According to Nietzsche, philosophy has been understood as an a priori discipline, a deliverance of pure reason. Given his empiricism, what role can he allow philosophy? In *Human, All Too Human* he claims to practise 'historical philosophy' and denies that it can be separated from natural science, suggesting that he counts empirical theories as philosophy if they illuminate topics of traditional philosophical concern. Attention to the more conceptual aspects of such theories might especially count as continuing the philosopher's traditional role (§§8–9 of this entry provide an example).

Further, Nietzsche's thinking on topics of traditional philosophical concern (§§4–5 of this entry) is philosophical in a more traditional sense, to the extent that it deals with conceptual as opposed to empirical matters. Such 'pure' philosophy is a matter of battling the images and pictures that beguile the mind and lead philosophers into thinking that there are purely philosophical questions to be answered concerning knowledge, truth and reality. Philosophy in this sense functions as therapy, and to the extent that Nietzsche practises it, he counts as a forerunner of Wittgenstein (see Wittgenstein, L.J.J. §§9–12).

Like Wittgenstein, Nietzsche gives language a major role in generating the problems and confusions of previous philosophy. He sometimes seems to criticize language itself for falsifying reality, holding the subject–predicate structure of Indo-European languages responsible for philosophers' propensity to think that reality itself must consist of ultimate subjects that could never be part of the experienced world: God and the ego, or indivisible atoms of matter. But he would probably say of language what he ultimately says of the senses: only what we make of their testimony introduces error. Language misleads us into traditional philosophy only if we erroneously assume that linguistic structure offers us a blueprint of reality that can be used to challenge the adequacy of empirical theories. This is similar to Wittgenstein's diagnosis that philosophical problems arise when language is taken away from the everyday tasks for which it is suited and expected to play a different game. Nietzsche's philosopher forces language to play the 'game' of affording insight into a non-empirical world.

Unlike Wittgenstein, however, Nietzsche fights the confusions of traditional philosophy to free us not *from* the need to do philosophy, but *for* what he considers the true task of genuine philosophy. And this task is not a matter of offering empirical theories. In his later work, Nietzsche insists that philosophers should not be confused with scholars or scientists, that scholarship and science are only means in the hands of the philosopher. Gradually it has become clear to him, he says, that philosophers' values are the 'real germ' from which their systems

grow. While pretending to be concerned only to discover truth, philosophers have actually been wily advocates for prejudices (values) they call 'truths'. They interpret the world in terms of their own values, and then claim that their interpretation, which they present as objective knowledge, gives everyone reason to accept these values – as the Stoics justified their ideal of self-governance on the grounds that nature itself obeys laws, an interpretation they arrived at by projecting their ideal of self-governance onto nature (*Beyond Good and Evil* §§1–9).

Because Nietzsche believes that interpretations of the world in terms of values provide something that is as important as truth, he wants the philosophy of the future to preserve this function of traditional philosophy. He does not, however, wish to preserve two aspects of the way in which previous philosophers have gone about this task: the lack of courage evident in their failure to recognize that they were reading values into the world rather than discovering truth, and the particular values they read into the world.

These values, he claims, have been expressions of the ascetic ideal, the ideal that takes the highest human life to be one of self-denial, denial of the natural self. Behind this ideal, which he finds in most major religions, Nietzsche locates the assumption that natural or earthly existence (the only kind he thinks we have) is devoid of intrinsic value, that it has value only as a means to something else that is actually its negation (such as heaven or nirvana). He claims that this life-devaluing ideal infects all the values supported by most religions (although *The Antichrist* retracts this in the case of Buddhism). Having come into existence in support of some form of life, values gain the support of the ascetic priest only if they are given a life-devaluing interpretation. Acts are interpreted as wrong or 'sinful', for instance, on the grounds that they are selfish or animal, that they affirm natural instincts. Traditional ('metaphysical') philosophers are successors to the ascetic priest because they interpret what they value – truth, knowledge, philosophy, virtue – in non-natural terms. In the background of their interpretations Nietzsche spies the assumption of the ascetic ideal: that whatever is truly valuable must have a source outside the world of nature, the world accessible to empirical investigation. What ultimately explains the assumption that philosophy must be a priori, and therefore concerned with a metaphysical world, is philosophers' assumption that nothing as valuable as philosophy or truth could be intimately connected to the senses or to the merely natural existence of human beings.

The philosophy of Nietzsche's early and middle periods can itself be diagnosed as an expression of the ascetic ideal. We can understand his devaluation of human knowledge in 'Truth and Lie' (his claim that human truths are 'illusions') as a response to the recognition that knowledge is rooted in the world of nature and thereby lacks the 'purity' demanded by the ascetic ideal. And we can surmise that he considered Darwinian naturalism dangerous because he saw that it deprives human life of value – if one accepts the ascetic ideal (see Darwin, C.R.). Indeed, when he embraced the truth of naturalism in *Human* (to the extent of accepting philosophy itself as an empirical discipline), he drew the conclusion that follows from the combination of naturalism and the ascetic ideal: that human life is without value. From the viewpoint of Nietzsche's later philosophy, it is hardly surprising that his early philosophy turns out to be another expression of the ascetic ideal. According to his *Genealogy*, the ascetic ideal is the only ideal of any widespread cultural importance human beings have had so far; it has dominated the interpretation and valuation of human life for millennia. To have escaped the ascetic ideal without having to work through its influence on him would have been impossible.

On the other hand, Nietzsche was also fighting the ascetic ideal. Naturalism works against the supernatural interpretation of human life that has been promoted by the ascetic ideal, and as modern science increasingly shows how much of the world can be understood in naturalistic terms, the influence of the ascetic ideal wanes. Or, rather, it goes underground. Nietzsche denies that science and the naturalism it promotes are themselves opposed to the ascetic ideal. The commitment to science is actually the latest and most noble form of the ascetic ideal, based as it is on the Platonic/Christian belief that God is truth, that truth is divine. This amounts to the assumption that truth is more important than anything else (for instance, life, happiness, love, power) an assumption Nietzsche traces to the ascetic ideal's devaluation of our natural impulses. Thus the development of science and naturalism has been promoted by inculcating the discipline of the scientific spirit – the willingness to give up what one would like to believe for the sake of what there is reason to believe – as the heir to the Christian conscience cultivated through confession. This has thereby worked against the exterior of the ascetic ideal, against the satisfaction it has provided – in particular, the sense that this life, and especially its suffering, has a meaning, that it shall be redeemed by another life. But to work against such satisfaction is not to oppose the ascetic ideal; it is simply to require more self-denial.

Nietzsche believes that we need a new ideal, a real alternative to the ascetic ideal. If philosophers

are to remain true to the calling of philosophy and not squander their inheritance, they must create new values and not continue merely to codify and structure the value legislations of ascetic priests. To create new values, however, it will be necessary for philosophers to overcome the ascetic faith that truth is more important than anything else, for truth is not sufficient support for any ideal. Although they must therefore overcome the ascetic ideal to create a new one, undertaking this task responsibly requires the training in truthfulness promoted by the ascetic ideal. The overcoming of the ascetic ideal that Nietzsche promotes is thus a self-overcoming.

7 The 'death of God' and nihilism

Nietzsche is perhaps best known for having proclaimed the death of God. He does in fact mention that God is dead, but his fullest and most forceful statement to this effect actually belongs to one of his fictional characters, the madman of *Gay Science*. Nietzsche's madman declares not only that God is dead and that churches are now 'tombs and sepulchres of God', but also that we are all God's 'murderers'. Although the madman may accept these statements as literally true, they clearly function as metaphors for Nietzsche. The 'death of God' is a metaphor for a cultural event that he believes has already taken place but which, like the death of a distant star, is not yet visible to normal sight: belief in God has become unbelievable, the Christian idea of God is no longer a living force in Western culture.

Nietzsche views all gods as human creations, reflections of what human beings value. However, pagan gods were constructed from the qualities human beings saw and valued in themselves, whereas the Christian God was given qualities that were the opposite of what humans perceived in themselves, the opposite of our inescapable animal instincts. Our natural being could then be reinterpreted as 'guilt before God' and taken to indicate our unworthiness. Constructed to devalue our natural being, the Christian God is a projection of value from the viewpoint of the ascetic ideal (see §6 of this entry). That this God is dead amounts to a prediction that Christian theism, along with the ascetic ideal that forms its basis, is nearing its end as a major cultural force and that its demise will be brought about by forces that are already and irreversibly at work.

One such force, to which Nietzsche himself contributed, is the development of atheism in the West, a development that stems from Christian morality itself and the will to truth it promotes. The will to truth, a commitment to truth 'at any price', is the latest expression of the ascetic ideal, but it also undermines the whole Christian worldview (heaven, hell, free will, immortality) of which 'God' is the symbol. Inspired by the will to truth, philosophy since Descartes has progressively undermined the arguments that supported Christian doctrines, and science has given us reason to believe that we can explain all the explicable features of empirical reality without appealing to God or any other transcendent reality. Theism has thus become cognitively superfluous. In this situation we can justify atheism without demonstrating the falsity of theism, Nietzsche claims, if we also have a convincing account of how theism could have arisen and acquired its importance without being true. Even if there is no cognitive basis for belief in God, however, might not one still accept something on the order of William James' will to believe? (see James, W.). Nietzsche nowhere treats this option as irrational, but he does deny that it is now a serious option for those who have taken most strictly and seriously Christianity's ascetic morality. It may not be irrational, but it is psychologically impossible, Nietzsche thinks, to accept theism if the commitment to truthfulness has become fully ingrained, if hardness against oneself in matters of belief has become a matter of conscience. Atheism is 'the awe-inspiring *catastrophe* of a two-thousand year discipline in truth that finally forbids itself the *lie involved in belief in God*' (*Genealogy* III §27).

Although atheism, especially among the most spiritual and intellectual human beings, undoubtedly weakens Christianity, depriving it of both creative energy and prestige, it does not bring about the death of God by itself. The modern world, as Kierkegaard had seen already, contains many other factors that weaken the influence of Christianity and its ideal; among these Nietzsche includes the development of money-making and industriousness as ends in themselves, democracy, and the greater availability to more people of the fruits of materialistic pursuits. Zarathustra's statement that 'when gods die, they always die several kinds of death' suggests that just as the ascetic ideal has been accepted by different kinds of people for different reasons, the death of God and the ascetic ideal is also brought about by a multiplicity of causes that operate differently on different kinds of people. What matters, says Zarathustra, is that 'he is gone' (*Zarathustra* IV §6).

According to Nietzsche, the loss of belief in God will initiate a 'monstrous logic of terror' as we experience the collapse of all that was 'built upon this faith, propped up by it, grown into it; for example, the whole of our European morality' (*Gay Science* §343). In notes made late in his career (published in *The Will to Power*), Nietzsche calls this collapse of values 'nihilism', the 'radical repudiation

of value, meaning, and desirability'. He predicts '*the advent of nihilism*' as 'the history of the next two centuries', and calls himself 'the first perfect nihilist of Europe'. However, he adds that he has 'lived through the whole of nihilism, to the end, leaving it behind' (*Will to Power* Preface). Nihilism is therefore not his own doctrine, but one he diagnoses in others (including his own earlier self). He *does not* believe that nothing is of value (or that 'everything is permitted') if God does not exist, but that this form of judgment is the necessary outcome of the ascetic ideal. Having come to believe that the things of the highest value – knowledge, truth, virtue, philosophy, art – must have a source in a reality that transcends the natural world, we necessarily experience these things as devoid of value once the ascetic ideal itself leads to the death of God, to the denial that any transcendent reality exists.

8 Morality

Nietzsche's criticism of morality is perhaps the most important and difficult aspect of his later philosophy. Calling himself an 'immoralist' – one who opposes all morality – he repeatedly insists that morality 'negates life'. He turned against it, he claims, inspired by an 'instinct that aligned itself with life' (*Birth of Tragedy* Preface). Whatever Nietzsche might mean by suggesting that morality is 'against life', his point is *not* that morality is 'unnatural' because it restricts the satisfaction of natural impulses. He finds what is natural and 'inestimable' in any morality in the hatred it teaches of simply following one's impulses, of any 'all-too-great freedom': it teaches 'obedience over a long period of time and in a single direction' (*Beyond Good and Evil* §188). Nietzsche analyses the directive to 'follow nature' as commanding something that is either impossible (if it means 'be like the nonhuman part of nature') or inevitable (if it means 'be as you are and must be').

His objection to morality sometimes seems to be not that it is 'against life', but that it promotes and celebrates a kind of person in which he finds nothing to esteem: a 'herd animal' who has little idea of greatness and seeks above all else security, absence of fear, absence of suffering. To complicate matters still further, he sometimes uses 'morality' to refer to what he approves of, for instance, 'noble morality' and 'higher moralities'.

The last of these interpretive problems can be resolved by recognizing that Nietzsche uses 'morality' in both a wider and a narrower sense. Every ethical code or system for evaluating conduct is 'a morality' in the wider, but not in the narrower sense. A system that determines the value of conduct solely in terms of 'the retroactive force of success or failure', for instance, is an instance of 'morality' in the wider sense, but Nietzsche counts it as 'pre-moral' in the narrower sense (*Beyond Good and Evil* §32). And it is the narrower sense Nietzsche is using when he commits himself to 'the overcoming of morality' and claims that it 'negates life'. His immoralism does not oppose all forms of ethical life. Although he opposes morality in the narrower sense, Nietzsche accepts another ethical system in terms of which he considers himself 'bound' or 'pledged'. Indeed, he claims that, contrary to appearances, 'we immoralists' are human beings 'of duty', having 'been spun into a severe yarn and shirt of duties [which we] *cannot* get out of' (*Beyond Good and Evil* §226).

Why didn't Nietzsche just say that he opposed *some* moralities and call his own ethical system his 'morality'? He undoubtedly thought that would be more misleading than his use of the term in a dual sense because it would trivialize the radical nature of his position. He called himself an 'immoralist' as a 'provocation' that would indicate what distinguishes him from 'the whole rest of humanity' (*Ecce Homo* IV §7). And it could so function, he thought, even though he actually opposes morality only in the narrower sense, precisely because this is the sense 'morality' has had until now. That word has been monopolized, he thinks, for a particular kind of ethical system on which all our currently available choices for an ethics are mere variations.

Genealogy provides a genealogy of morality in the narrower sense (the sense 'morality' will have hereafter in this entry) and a complex and sophisticated analysis of that concept of morality. Although there is no agreed-upon definition, we all have a feeling for what 'morality' in this sense means. But both the feeling and the 'meaning' are actually products of a complicated historical development that synthesized meanings of diverse origins into a unity, one that is difficult to dissolve or analyse and impossible to define. If conceptual analysis were a matter of formulating necessary and sufficient conditions for the use of a term, we might analyse the concept of morality by specifying the characteristics that are both necessary and sufficient to qualify a code of conduct as 'a morality'. But this approach has never delivered great clarification, and Nietzsche's understanding of concepts explains why: our concepts need clarification precisely because they are products of a complicated historical development. Different strands have been tied together into such a tight unity that they seem inseparable and are no longer visible as strands. To analyse or clarify such a concept is to disentangle these strands so that we can see what is actually involved in the concept. History can play a role in analysing a concept because at earlier stages the

'meanings' that constitute it are not as tightly woven together and we can still perceive their shifts and rearrangements. Looking at the history of the corresponding phenomenon can therefore make it easier for us to pick out the various strands that make up the concept and better able to recognize other possible ways of tying them together. Nietzsche's genealogy of morality aims to show that there are distinct aspects of morality, each with a separate pre-moral source, which makes the synthesis we call 'morality' something that can be undone, so that its strands might be rewoven into a different form of ethical life.

The three essays of *Genealogy* separate out for examination three main strands of morality: the good (in the sense of virtue), the right (or duty), and a general understanding of value. Each essay focuses on the development of one strand without paying much attention to the other two, even though any developed form of ethical life will actually involve all three aspects in some form and interconnection. The overall account of morality constitutes a 'genealogy' precisely because it traces the *moral* version of each strand back to pre-moral sources – thus to *ancestors of morality.* Its upshot is that what we call 'morality' emerged from these pre-moral ancestors when the right and the good become tied together under the interpretation of value provided by the ascetic ideal. This explains why Nietzsche claims that morality 'negates life': morality is an ascetic interpretation of ethical life.

The first essay in *Genealogy* finds the central pre-moral ancestor of morality's idea of goodness among politically superior classes in the ancient world whose members called themselves 'the good' and used 'good' and 'virtue' as their marks of distinction, the qualities that distinguished them from commoners or slaves. 'Good' and 'virtuous' were the same as 'noble' in the sense of 'belonging to the ruling class'; their contrasting term was 'low-born' or 'bad' (the German, *schlecht*, originally meant 'simple' or 'common').

As Nietzsche uses 'bad' (he does not claim to reflect contemporary usage), it involves no connotation of blame, whether applied to the poor person or the liar. 'Bad' certainly expresses a value judgment: that the person so described is inferior. The nobles regard themselves as superior and look down on the bad (sometimes with contempt, sometimes with pity). But they do not blame them for being inferior, or think that the inferior ought to be good (much less that inferiority deserves punishment or goodness a reward). Such judgments make sense only if one is judging inferiority in moral terms – that is, if 'bad' has become 'morally bad' or 'evil'.

To explain the origin of the good/evil (the specifically moral) mode of valuation, Nietzsche postulates a 'slave revolt in morality', a revaluation inspired by *ressentiment* (grudge-laden resentment) against the nobles. Nietzsche does not claim that the nobles' actions were considered wrong because they were resented. He is dealing only with ideas of goodness or virtue in this essay; he seeks to explain how goodness became connected to praise and blame, reward and punishment. His postulated 'slave revolt' was led not by slaves but by priests, the 'great haters' in human history precisely because their spirituality is incompatible with the direct discharge of resentment and revenge. They hated the nobles not because they were oppressed by them but because the nobles considered themselves superior and had been victorious over them in gaining the respect and admiration of the people. Because this hatred could not be expressed directly, it grew to monstrous proportions until it finally found an outlet in revaluing the nobles and their qualities as inferior. As a result, certain qualities – useful to those in a slavish or dependent position – were called 'good', not because anyone found them particularly admirable, but from a desire to 'bring down' people with the opposite qualities. Simply 'looking down' at the nobles and their qualities would not have done the trick, especially since the majority envied and admired them. Only through the transformation of bad into evil, of inferiority into something for which one could be blamed, could the revaluation succeed. Pent-up *ressentiment* could then be vented in acts of blaming and moral condemnation, which Nietzsche sees as acts of 'imaginary revenge' that 'bring down' hated opponents 'in effigy' and elevate those who do the blaming, at least in their own imagination. Blaming, for Nietzsche, evidently involves the judgment that the person blamed is deserving of punishment, in this case for their inferiority. Therefore, once 'bad' is transformed into 'evil', God and his judgment along with heaven and hell can be used to support the revaluation by winning over to it those who would not feel sufficiently elevated by mere moral condemnation of the nobles. Nietzsche suggests that this is how the issue of free will became connected to morality. Blaming or holding people responsible for their actions does not raise the issue; it is raised by holding them responsible for what they are. And that is precisely what was required for the revaluation of noble values.

9 Morality (cont.)

Priests did not invent the idea of 'evil' on the spot, however. The notion of blame required for the revaluation emerged in a quite different sphere, that of right conduct or duty, the development of which

Nietzsche sketches in the second essay of *Genealogy*. The pre-moral ancestor to which this essay traces moral versions of right and wrong, duty or obligation, is the ethics of custom (*Sittlichkeit der Sitte*), an early system of community practices that gained the status of rules through the threat of punishment. These rules were perceived as imperatives, but not as moral imperatives: violation was punished, but not considered to be a matter of conscience or thought to incur guilt.

Nietzsche finds an ancestor of guilt in the realm of trade, in the creditor–debtor relation. Guilt arises, Nietzsche claims, when the idea of debt is put to the uses of the 'bad conscience', the sense of oneself as unworthy, which develops when the external expression of aggressive impulses becomes restricted to such an extent that they can be expressed only by being turned back against the self. This internalization does not take place automatically, however; human beings must learn techniques that promote it, and Nietzsche views priests as the great teachers in this field. One such technique exploits the idea that a debt is owed to ancestors (who eventually come to be perceived as gods) for the benefits they continue to bestow and for violations of community laws which represent their will. Priests use this idea to teach the people that they must make difficult sacrifices to the gods – for example, to sacrifice one's first-born – and that certain instances of apparent bad luck and suffering constitute the extraction of payment for violations of divine law, hence are deserved punishments.

So conceived, the debts are still mere debts, material rather than moral 'owings'. The moralization of debt (and thereby of duty) removes the idea that it can simply be paid off and connects it to one's worth or goodness. This moralization takes place by means of the third strand of morality analysed in *Genealogy*, the understanding of value, which in the case of morality is guided by the ascetic ideal. We enter what Nietzsche calls the 'moral epoch' only when the divine being to whom the debt is owed is considered the highest being and is conceived in non-naturalistic or ascetic terms, as a purely spiritual being and thus as a repudiation of the value of natural human existence (see §§6–7 of this entry). What must now be sacrificed to the divine is 'one's own strongest instincts, one's "nature"' (*Beyond Good and Evil* §55). The affirmation of these instincts is conceived as rebellion against God, and the normal sufferings of human life as punishments for this rebellion. The debt is now owed precisely for what one is and continues to be, for being part of the natural world. This debt can no longer be considered material, a mere debt, for while it is owed and payment must be made, it can never be paid off. And the punishment one deserves is now completely bound up with one's (lack of) goodness or virtue, which is interpreted in ascetic terms as self-denial, the denial of one's natural impulses, or at least as selflessness.

The priest now has the notion of 'evil' required for the revaluation of the noble values: the moralized notion of virtue as self-denial provides the standard against which the nobles could be judged inferior, whereas the moralized notion of debt provides the basis for blaming the nobles for that inferiority. Both notions (of virtue and duty) were moralized by being tied together under the understanding of value provided by the ascetic ideal. Morality connects duty and virtue in such a way that blameable violations of duty are taken to show lack of virtue and lack of virtue is blameable (luck has nothing to do with it). Because he sees this connection as having been brought about by means of the ascetic ideal, Nietzsche regards that ideal as a major element of morality.

His own ideal is a very different one. Named after the Greek god Dionysus, Nietzsche's ideal celebrates the affirmation of life even in the face of its greatest difficulties, and thus gives rise to a doctrine and valuation of life that is fundamentally opposed to the one he finds behind morality. Committed to finding the sources of value in life, he rejects all non-naturalistic interpretations of ethical life, those that make reference to a transcendent or metaphysical world. It therefore seems likely that what he opposes in morality is not the idea of virtue, or standards of right and wrong, but the moralization of virtue and duty brought about by the ascetic ideal. Morality 'negates life' because it is an ascetic interpretation of ethical life. By interpreting virtue and duty in non-natural terms, it reveals the assumption of the ascetic ideal: that things of the highest value must have their source 'elsewhere' than in the natural world. This is why Nietzsche says that what 'horrifies' him in morality is 'the lack of nature, the utterly gruesome fact that *antinature* itself received the highest honours as morality and was fixed over humanity as law and categorical imperative' (*Ecce Homo* IV §7).

But how is this connected to Nietzsche's complaints against 'herd morality'? 'Herd' is his deliberately insulting term for those who congregate together in questions of value and perceive as dangerous anyone with a will to stand alone in such matters. He calls the morality of contemporary Europe 'herd animal morality' because of the almost complete agreement 'in all major moral judgments'. Danger, suffering, and distress are to be minimized, the 'modest, submissive, conforming mentality' is honoured, and one is disturbed by 'every severity, even in justice'. Good-naturedness and benevolence are valued, whereas the 'highest and strongest

drives, if they break out passionately and drive the individual far above the average and the flats of the herd conscience', are slandered and considered evil (*Beyond Good and Evil* §§201–2).

This morality does not seem to involve the ascetic ideal. In fact, it is more likely to be packaged as utilitarianism, which offers a naturalistic, and therefore presumably unascetic, interpretation of duty and virtue in terms of happiness (see UTILITARIANISM). We might, in fact, formulate Nietzsche's main objection to herd morality as a complaint that there is nothing in it to play the role of the ascetic ideal: to hold out an ideal of the human person that encourages individuals to take up the task of self-transformation, self-creation, and to funnel into it the aggressive impulses, will to power and resentment that would otherwise be expressed externally. Although it horrifies him, Nietzsche recognizes the greatness of the ascetic ideal. It is the only ideal of widespread cultural importance human beings have had so far, and it achieved its tremendous power, even though it is the 'harmful ideal *par excellence*', because it was necessary, because there was nothing else to play its role. 'Above all, a counterideal was lacking – until Zarathustra' (*Ecce Homo* III GM).

The problem is that the ascetic ideal is now largely dead (as part of the 'death of God'). Nietzsche thinks we need something to replace it: a great ideal that will inspire the striving, internalization, virtue, self-creation that the ascetic ideal inspired. 'Herd animal morality' is what we are left with in the absence of any such ideal. It is what morality degenerates into once the ascetic ideal largely withdraws from the synthesis it brought about. The virtuous human being no longer is anything that can stir our imagination or move us. For Nietzsche, this is the 'great danger' to which morality has led: the sight of human beings makes us weary.

*10 The overhuman (*Übermensch*)*

Nietzsche's apparent alternative to 'herd-animal morality' is his most notorious idea, the *Übermensch*. (There is no really suitable English translation for this term: 'overhuman' has been chosen instead of 'superman' or 'overman' because it seems best able to bring out the idea of a being who overcomes in itself what has defined us as human.) The idea actually belongs to the protagonist of *Thus Spoke Zarathustra*, Nietzsche's work of philosophical fiction, and it can never be assumed that Zarathustra's ideas are the same as those of Nietzsche. As the story opens, Zarathustra is returning from ten years of solitude in the wilderness, bringing human beings a gift: his teaching that humanity is not an end or goal, but only a stage and bridge to a higher type of being, the overhuman. He teaches that now that God is dead, it is time for humanity to establish this higher type as the goal and meaning of human life, a goal that can be reached only if human beings overcome what they now are, if they overcome the merely human.

The idea of becoming a higher kind of being by overcoming one's humanity can seem frightening. For some, it calls up images of Nazi stormtroopers seeking out 'inferior' human beings to annihilate. However, *Zarathustra* suggests that Nietzsche has something very different in mind. 'Zarathustra' is another name for Zoroaster, the founder of Zoroastrianism (see ZOROASTRIANISM). Nietzsche claims that the historical Zarathustra 'created the most calamitous error, morality', because his doctrine first projected ethical distinctions into the metaphysical realm (as a cosmic fight between good and evil forces). Nietzsche bases his character on Zarathustra because the creator of the error 'must also be the first to recognize it' (*Ecce Homo* IV §3).

Zarathustra is thus the story of a religious leader, the inventor of one of the world's oldest religions, who comes to recognize the 'error' of traditional (moralized) religions. Far from turning against every aspect of traditional religion, however, Zarathustra commits himself to its central task: urging human beings to raise their sights above their usual immersion in materialistic pursuits to recognize the outlines of a higher form of being that calls them to go beyond themselves, to become something more than they are. Zarathustra's overhuman can thus be seen as a successor to the images of 'higher humanity' offered by traditional religions. His teaching is not intended to encourage human beings to throw off the constraints and shackles of morality (something Nietzsche sees as well underway without his help). Its point is, rather, to combat the forces of barbarism by encouraging us to take on a more demanding ethical task than modern morality requires: that of becoming what Nietzsche had earlier called a 'true human being'. When he used that phrase, however, Nietzsche believed it applied only to 'those no-longer animals, the philosophers, artists, and saints'. Animal (purely natural) existence was a senseless cycle of becoming and desire, and only those who escape it by extinguishing egoistic desire counted as truly human. The saint in particular counted as 'that ultimate and supreme becoming human', in which 'life no longer appears senseless but appears, rather, in its metaphysical meaningfulness' (*Unfashionable Observations* III §5). From the viewpoint of his later philosophy, early Nietzsche's conception of true humanity is an obvious expression of the ascetic ideal; it devalues natural existence relative to something that is its

opposite. Once one recognizes this opposite as unattainable (as Nietzsche did in *Human*), the conception can be seen for what it really is: a devaluation and condemnation of human life.

Nietzsche never abandoned his early belief that the modern world is threatened by forces of both conformism and barbarism and that our great need is therefore for educators who will inspire human self-overcoming by the force of a lofty ideal. But since he rejects the ascetic ideal, he must abandon his earlier image of a true human being. At the end of *Genealogy*'s second essay, Nietzsche suggests that what the overhuman overcomes is not the 'natural' inclinations against which the ascetic ideal has been directed, those that make apparent our connection to other animals, but rather the 'unnatural' inclinations, the aspirations to a form of existence that transcends nature and animality. In other words, the overhuman must overcome all the impulses that led human beings to accept the ascetic ideal, an ideal that has so far defined what counts as 'human'. As we will see in §2, however, Zarathustra's call for the overcoming of the human is still too bound up with the old ideal.

11 The will to power

Zarathustra teaches that life itself is will to power, and this is often thought to be Nietzsche's central teaching as well. However, will to power first appears in Nietzsche's work in *Daybreak* (1881), and there it is one human drive among others, the striving for competence or mastery. It is usefully thought of as a second-order drive or will: a need or desire for the effectiveness of one's first-order will. In *Daybreak*, Nietzsche finds this drive at work in large areas of human life: in asceticism, revenge, the lust for money, the striving for distinction, cruelty, blaming others, blaming oneself. He explains the drive's apparent omnipresence in human life by saying not that life is will to power (or that power is the only thing humans want), but that power has a special relation to human happiness. He calls love of power a 'demon' because human beings remain unhappy and low-spirited if it is not satisfied even if all their material needs are satisfied, whereas power can make them as happy as human beings can be, even if everything else is taken away (*Daybreak* §262). In *Genealogy* (1887) he expresses a similar idea in more positive terms when he calls the will to power 'the most life-affirming drive', that is, the one whose satisfaction contributes most to finding life worth living (*Genealogy* III §18).

Zarathustra claims that this 'will to be master' is found in all that lives, and that this explains why life is 'struggle and becoming', always overcoming itself, always opposing what it has created and loved: 'Verily, where there is perishing and a falling of leaves, behold, there life sacrifices itself – for power' (*Zarathustra* II §12). But this seems a clearly anthropomorphic conception of life, the projection of the human will to power onto nonhuman nature. Nietzsche rejects anthropomorphic conceptions of nature, insists that will is to be found only in beings with intellects, and complains that Schopenhauer's idea of will 'has been turned into a metaphor when it is asserted that all things in nature possess will' (*Human* II §5).

Yet Nietzsche does say that life, and even reality itself, is will to power. The idea seems to be that reality consists of fields of force or dynamic quanta, each of which is essentially a drive to expand and thus to increase its power relative to all other such quanta. However, almost all the passages to this effect are found in Nietzsche's notebooks. He actually argues that reality is will to power in only one passage he chose to publish, and this passage gives us good reason to doubt that Nietzsche actually accepted the argument. He neither says nor implies that he accepts its conclusion, and he argues against its premises in earlier passages of the same book (*Beyond Good and Evil* §36).

Why would Nietzsche construct a rather elaborate argument from premises he clearly rejects? Perhaps it was to illustrate the view of philosophy presented earlier in the same book. Philosophers' ultimate aim, he claims, is not to obtain knowledge or truth, but to interpret the world in terms of their own values (see §6 of this entry) – to 'create [in thought] a world before which [they] can kneel' (*Zarathustra* II §12). Yet they present their interpretations as true, and argue for them on the basis of amazingly 'little': 'any old popular superstition from time immemorial', a play on words, a seduction by grammar, or 'an audacious generalization of very narrow, very personal, very human, all too human facts' (*Beyond Good and Evil* Preface). This seems an apt diagnosis of Nietzsche's own argument, since he elsewhere identifies its first premise as 'Schopenhauer's superstition' and the exaggeration of a popular prejudice, and its second and third premises as part of the 'primeval mythology' Schopenhauer 'enthroned' (*Beyond Good and Evil* §§16–19; *Gay Science* §127). Furthermore, the effect of the argument is an 'audacious generalization' to the whole universe of the will to power, which Nietzsche originally understands as one human drive among others. In generalizing this drive, Nietzsche can be seen as generalizing and glorifying what he values, just as he claims philosophers have always done and must do. For Nietzsche's own answer to 'what is good?' is 'everything that heightens the feeling of power in human beings, the will to power, power itself' (*Antichrist* §2).

Why does Nietzsche value the will to power? He certainly came to recognize it as responsible for the violence and cruelty of human life and as the prime ingredient in what he had earlier called the 'cauldron full of witches' brew' that threatens the modern world with 'horrible apparitions' (*Unfashionable Observations* III §4). But he also saw it as 'the most life-affirming drive' and as responsible for the great human accomplishments – political institutions, religion, art, morality and philosophy. His basic psychological claim is that human beings are subjected to intense experiences of powerlessness and that such experience leads to depression unless some means is found for restoring a feeling of power. What we call 'barbarism' is largely a set of direct and crude strategies for restoring the feeling of power by demonstrating the power to hurt others. What we call 'culture' is a set of institutions and strategies for achieving the same feeling in a sublimated or less direct fashion. The most important strategies have all involved directing the will to power back against the self. Such internalization is responsible for all the ethical achievements of human life, all the ways in which human beings have changed and perfected their original nature by taking on a new and improved nature. But the internalization of the will to power has been promoted by the ascetic ideal's condemnation of our original nature, especially of the will to power. This is what Zarathustra attempts to overcome with his overhuman teaching, which directs the will to power back against the self to overcome the inclinations that led to the old ideal. He therefore does not condemn the will to power, but celebrates it.

12 Eternal recurrence

Nietzsche identifies himself above all else as the teacher of eternal recurrence, which is often interpreted as a cosmological theory to the effect that the exact history of the cosmos endlessly repeats itself. Although he did sketch arguments for such a theory in his notebooks, he actually does not argue for or commit himself to a recurrence cosmology in any work he published. And, although he presents eternal recurrence as the 'basic conception' of *Zarathustra*, he does not commit its protagonist to a cosmology. He identifies this 'basic conception' not as a cosmology, but as 'the highest formula for affirmation that is at all attainable' (*Ecce Homo* III §1).

As first articulated in *Gay Science*, eternal recurrence is a heuristic device used to formulate Nietzsche's Dionysian ideal (see §9 of this entry). How well disposed we are to life is to be measured by how we would react upon being told by a demon (in a manner designed to induce uncritical acceptance) that we will have to live again and again the exact course of life we are now living. Would we experience despair or joy, curse the demon or greet him as a god? Nietzsche's ideal is the *affirmation of eternal recurrence*, to be a person who would respond to the demon with joy. This is *not* equivalent to having no regrets, since it has no implication concerning how to respond if given the choice of variations on history. Nietzsche's ideal is to love life enough to be joyfully willing to have the whole process repeated eternally, including all the parts that one did not love and even fought against. Eternal recurrence gives him a formula for what it is to value the process of life as an end and not merely as a means.

Nietzsche's special self-identification with eternal recurrence can be explained in terms of his view regarding the importance of the ascetic ideal and his explanation of its power: 'a *counterideal* was lacking – until Zarathustra'. There are only two plausible candidates for the counterideal Zarathustra offers: the overhuman and the affirmation of eternal recurrence. The overhuman is one who overcomes the ascetic ideal. But, as Zarathustra first preaches it, the overhuman ideal can be seen as another variation on the ascetic ideal. Like the ascetic priest, Zarathustra treats our lives as valuable only as a means to a form of life that is actually their negation. Like the ascetic priest, he turns his will to power against human life and takes revenge against it (for the powerlessness it induces) by excluding it from what he recognizes as intrinsically valuable. The ideal of affirming eternal recurrence, in contrast, values the whole process of living, and thereby overcomes the ascetic ideal's devaluation of human life, even while pushing us to go beyond its present form. It provides us with the image of a higher form of human life, but does not take revenge against the latter by refusing to call its higher form 'human'. It therefore appears to be Zarathustra's true alternative to the ascetic ideal.

It may seem, however, that happy pre-moral barbarians should be able to affirm eternal recurrence. How then can it provide an image of a higher form of human life towards which to strive, one that could inspire internalization, virtue and self-creation comparable to that inspired by the ascetic ideal? One relevant factor is Nietzsche's hope for new philosophers who will create new values. Perhaps he did not expect his counterideal to provide the full content of new values, just as the ascetic ideal did not provide the full content of the old values. The ascetic priests did not create their values from scratch. They took over virtues, duties, forms of life that were already there and gave them a new interpretation, one that denied the value of natural human existence. Nietzsche seems to hope that new philosophers will do something comparable – that

they will provide a new life-affirming interpretation of virtues, duties and forms of life that are already there. Eternal recurrence would function as the form of new values, a test that they must pass to count as non-ascetic or life-affirming. The test for teachers of new values would be: can you endorse and teach these values while affirming eternal recurrence?

If this suggestion is correct, Nietzsche's relation to the modern world is not quite as revolutionary as it sometimes appears. The role of his new philosophers is not to overturn everything, but to take what is in pieces due to the dissolution of the old interpretation of value and to provide a new interpretation. This kind of philosophizing is not just for the future, but is found in Nietzsche's own writings. He praises old virtues – justice and generosity, for instance – but gives us a new interpretation of them, a different way of seeing them as valuable. Generosity is valuable not because it is selfless, but because it exhibits the soul's richness and power. And justice is perhaps the greatest virtue not because it is disinterested or obeys a higher law, but because it is the rarest and highest mastery that is possible on earth. And Nietzsche does not merely talk about these matters. His writings show us a new kind of person and a new kind of philosopher in the virtues he exhibits in them, not least of all in the interpretations he gives of his virtues. Truthfulness or honesty, justice, generosity are all exhibited in his writings, but are given life-affirming interpretations that bring to our attention the role of the will to power in them.

This is not to say that Nietzsche's new values are simply repackaged old ones. Nietzsche's ideal leads him to value qualities that he claims have never before been considered part of greatness, such as malice, exuberance and laughter. But even in their new interpretations of old values, the aim of Nietzsche's new philosophers is to push culture in new directions, for instance, towards giving explicit expression at the higher levels of culture to what the old ideal excluded from the highest forms of life. This is what Nietzsche exhibits, for instance, in the positive and negative emotion, the exuberance and malice, the aggression and eros, that permeates his writings. At this level, his philosophy is art, but it is an art that completes and is no longer used to devalue knowledge, which can now be recognized as its sometimes contentious partner in Nietzsche's soul and writings.

NIHILISM

As its name implies (from Latin *nihil*, 'nothing'), philosophical nihilism is a philosophy of negation, rejection, or denial of some or all aspects of thought or life. Moral nihilism, for example, rejects any possibility of justifying or criticizing moral judgments, on grounds such as that morality is a cloak for egoistic self-seeking, and therefore is a sham; that only descriptive claims can be rationally adjudicated and that moral (prescriptive) claims cannot be logically derived from descriptive ones; or that moral principles are nothing more than expressions of the subjective choices, preferences or feelings of the people who endorse them.

Similarly, epistemological nihilism denies the possibility of justifying or criticizing claims to knowledge, because it assumes that a foundation of infallible, universal truths would be required for such assessments, and no such thing is available; because it views all claims to knowledge as entirely relative to historical epochs, cultural contexts or the vagaries of individual thought and experience, and therefore as ultimately arbitrary and incommensurable; because it sees all attempts at justification or criticism as useless, given centuries of unresolved disagreement about disputed basic beliefs even among the most intelligent thinkers; or because it notes that numerous widely accepted, unquestioned beliefs of the past are dismissed out of hand today and expects a similar fate in the future for many, if not all, of the most confident present beliefs.

Political nihilism calls for the complete destruction of existing political institutions, along with their supporting outlooks and social structures, but has no positive message of what should be put in their place. Cosmic nihilism regards nature as either wholly unintelligible and starkly indifferent to basic human concerns, or as knowable only in the sense of being amenable to scientific description and explanation. In either case, the cosmos is seen as giving no support to distinctively human aims or

values, and it may even be regarded as actively hostile to human beings. Existential nihilism negates the meaning of human life, judging it to be irremediably pointless, futile and absurd.

DONALD A. CROSBY

NINETEENTH-CENTURY PHILOSOPHY

Introduction

In the first part of the nineteenth century, the reigning philosophical outlook was idealist in one form or another, as the attempt was made to complete the intellectual revolution which Kant had begun, but which he was seen as having compromised in a variety of ways. Culminating in the dominance of Hegel and Hegelianism in the 1830s, this idealist position was criticised in the second half of the century from a number of perspectives, including Neo-Kantianism (which sought a return to an idealism closer to Kant's own), materialism (which rejected idealism altogether) and positivism (which sought to revive elements of empiricism that Kant had put in doubt). Nonetheless, idealism never fully lost its influence, and there are interesting and important cross-currents between all these positions throughout the nineteenth century. From our present viewpoint many of these debates can be seen to foreshadow contemporary controversies, such as those between naturalism and transcendentalism, and between various forms of idealism and realism, as well as wider issues concerning the nature of philosophy and the relation between science and religion.

1 From the eighteenth to the nineteenth century

In his *Autobiography* (written in the 1850s and 1860s), J.S. MILL famously identified 'the reaction of the nineteenth century against the eighteenth' as a central feature of intellectual life in this period. The 'reaction' he is referring to is the way in which many early nineteenth-century thinkers saw the Enlightenment conception of reason, naturalism and liberalism as leading to scepticism, materialism and anarchy; if rationalism, science and freedom were to be defended, they argued, it could only be achieved against the background of some kind of idealism, which required thinking about religion, nature, and the social and historical world in a new way. To their critics, however, this claim by the idealists who sought to question the outlook of the eighteenth century was no more than a cover for a return to the kind of reactionary metaphysical thinking that the Enlightenment had swept away; these critics therefore sought to defend empiricism, the authority of science, and naturalism against these charges, and so began a counter-reaction on behalf of the ideals of the eighteenth century. Mill characterizes the struggle this engendered in a memorable image: 'The fight between the nineteenth century and the eighteenth always reminded me of the battle about the shield, one side of which was white and the other black. I marvelled at the blind rage with which the combatants rushed against one another' (in *Autobiography*). (See ENLIGHTENMENT, CONTINENTAL)

The origins of this struggle can be found in the eighteenth century itself, and can be traced back to KANT, who thus remains a key figure in the nineteenth century. While at one level Kant was deeply committed to the ideas of the eighteenth-century Enlightenment – freedom, reason, Newtonian science, religious toleration – it appeared to him that the epistemology and metaphysics of the Enlightenment – empiricism, realism, materialism – led to the undermining of these ideals, as freedom was threatened by causal determinism, reason and science were threatened by scepticism, and religion by dogmatic materialism and militant atheism. Kant therefore sought to retain the Enlightenment ideals, but to overturn the epistemology and metaphysics that seemed to undermine them. His solution was what he called 'transcendental idealism', where the strategy was to argue that scepticism, determinism and atheism can be avoided once the empirical world is treated as an appearance: scepticism is thus avoided, because we can now be sure that this world will conform to our concepts; determinism is thus avoided, because causality only operates in the sphere of appearances and not in relation to things in themselves, where the self is located; and atheism can be avoided, because we can still postulate the existence of God and immortality and so leave room for faith. However, in preserving the ideals of the Enlightenment in this way, Kant was consciously overturning its epistemology and metaphysics: he

argued that experience no longer gives us access to a mind-independent reality that is purely material and causally determined; rather, what we experience this way is only the world as it appears to us. Nonetheless, he tried to sweeten the pill by pointing out that the empiricists and materialists themselves had accepted that this was true of many aspects of the world that common-sense takes to be straightforwardly real, such as colour and taste; all he was doing was applying the same idea at a higher level, to matter in time and space itself. Once this step was taken, he argued, it could be seen that pushed to their limit, empiricism and materialism themselves lead to transcendental idealism, and that it is therefore the natural next stage of Enlightenment thinking.

For those who came after Kant in the nineteenth century – such as the German idealists FICHTE, SCHELLING and HEGEL; the young Romantics Hölderlin, NOVALIS and SCHLEGEL; and the Protestant theologian Schleiermacher – the general project was the same, and the diagnosis was shared; but the Kantian solution was rejected. That is, for this generation of thinkers it was clear that despite its high ideals, the Enlightenment outlook of the British empiricists and the French encyclopedists was threatened by collapse into scepticism, materialism and nihilism. Likewise, they shared with Kant a sense that the fault lay with the metaphysics and epistemology of the eighteenth-century thinkers. However, they felt that as it stood, Kant's appeal to transcendental idealism as an alternative was inadequate, in part because in itself was too much indebted to the eighteenth-century outlook it had sought to transcend, with its atomistic view of experience, its scepticism about the world as it is in itself and its commitment to Newtonian mechanics as a scientific paradigm. (This dissatisfaction with Kant was influenced in part by the somewhat earlier critique of his work offered by Jacobi, Hamann and HERDER, amongst others.) In different ways, therefore, these post-Kantians sought other solutions to the crisis in eighteenth-century thought that Kant had been responding to, as it was agreed that Kant's radically dualistic picture of appearances and 'the thing-in-itself' could not avoid collapsing into scepticism, determinism and atheism. (Although ignored at the time, the only major thinker in this period who was still trying to work largely within the Kantian framework was SCHOPENHAUER, while outside Germany Kant continued to find followers, for example ROSMINI-SERBATI in Italy.)

2 *Nineteenth-century idealism*

While the post-Kantian German idealists and Romantics had a shared sense of the difficulties to be overcome, and of the way in which Kant himself had failed to resolve these difficulties, they differed amongst themselves over what alternative solution to propose, and the struggle between them was at times intense (see GERMAN IDEALISM). In terms of historical influence, however, there is no doubt that Hegel emerged as the thinker with the greatest impact in the 1820s and 1830s, both within his native Germany and through much of the rest of Europe and, later, America (see BAKUNIN, M.A.; BELINSKII, V.G.; COUSIN, V.; HEGELIANISM), although Schelling also had a following outside Germany during this period, as did KRAUSE in Spain and Argentina.

However, if it appeared to some that Hegel had brought the great cycle of Western thought to a satisfactory close, and that there would be no going further or back, this sense was quickly lost, partly because difficulties and tensions emerged as Hegel's thought was increasingly questioned, and partly because from the 1840s onwards there was an increasing revival of the eighteenth-century outlook that idealism had seemed to have eclipsed. Thus, on the one hand, Hegel's grand synthesis faced critique and reform at the hands of a series of younger radical thinkers such as FEUERBACH, Hess, Ruge, Bauer, Cieszkowski, HERZEN, MARX, Heine and KIERKEGAARD, some of whom were inspired in part by Schelling's attack on Hegel after the latter's death (see SCHELLING), and by other critics such as TRENDELENBURG; on the other hand, it appeared that the idealist critique of eighteenth-century thought as leading to determinism, immoralism, atheism and scepticism was misguided – or, if it were right, just had to be accepted and lived with, as the harsh but inescapable truth concerning the world and our place within it. Deprived of its underlying motivation, post-Kantian idealism now appeared as reactionary, simply trying to obscure the fundamental truths that the eighteenth century empiricists and materialists had uncovered: namely, that we are natural creatures living in a godless universe governed by scientific laws, to which experience gives us adequate but limited access. The most profound thinkers of the second half of the nineteenth century – such as Marx, Mill and NIETZSCHE – can be seen as struggling to come to terms with and find something progressive in this conclusion, without requiring any return to idealism.

3 *The turn against idealism: materialism, positivism, empiricism, naturalism*

After the authority of Hegelian idealism was questioned from the 1840s onwards, the remainder of the century is marked by a battle between those who sought to go back to the eighteenth century

and re-think the doctrines of LOCKE, HUME, BENTHAM or the French materialists, and those who believed that this was a retrograde step, which could only lead to the same mistakes and with them a threat to freedom, reason, morality and religion.

Perhaps the most obvious sense in which the second half of the nineteenth century saw a return to the eighteenth was in the way that the major movements of the period – materialism, positivism, empiricism – went back to a conception of science and of science's relation to philosophy that belonged to the seventeenth and eighteenth centuries, when the scientific revolution had decisively shaped philosophical thinking. It would be wrong to characterize the German idealism of the first half of the nineteenth century as crudely 'anti-scientific'; nonetheless, it did see itself as opposed to the scientific paradigms of the seventeenth and eighteenth centuries, particularly Newtonianism. In the early nineteenth century, the new approach of NATURPHILOSOPHIE, espoused primarily by Schelling, GOETHE and Hegel, in fact became the favoured scientific outlook with some researchers, and bore real fruit in the work of Lorenz Oken, Hans Christian Ørsted, and Johann Wilhelm Ritter, amongst others; but in the second half of the nineteenth century, this idealist *Naturphilosophie* was viewed as mere metaphysical speculation, divorced from true science, which was once again seen as requiring a commitment to the mechanistic paradigms of explanation which the *Naturphilosophen* had sought to question. Thus, in relation to the natural sciences in the second half of the nineteenth century, philosophy can be seen as returning to positions it had adopted previously, when under the influence of the scientific revolution in the seventeenth and eighteenth centuries.

In the eighteenth century, one way in which that influence was most directly felt was in the conception philosophers came to have of the ultimate nature of reality, as physicalistic, mechanistic and deterministic. This view was adopted by the radical *philosophes* of the Enlightenment, particularly Julien de LA METTRIE and Paul d'Holbach, who were uncompromising in their scientific materialism. While aiming to overcome the Cartesian dualism of mind and matter, they also (and much more broadly) saw the material world in essentially mechanistic terms. They also used the authority and methods of science to challenge all metaphysical speculation and apriorism, and instead defended a thoroughgoing empiricism. Likewise, materialism in the nineteenth century came to adopt a similar view, taking this to be the lesson of contemporary science, which they saw as continuous with seventeenth- and eighteenth-century physicalism. The thinking of La Mettrie and d'Holbach thus has its nineteenth-century counterpart in the work of Carl Vogt, Jacob Moleschott, Ludwig BÜCHNER and Heinrich Czolbe in Germany; John Tyndall in Britain; and Nikolai Chernyshevskii in Russia (see also NIHILISM). The impact of DARWIN and Darwinism also played a vital role in underlining the authority of this broadly materialist and naturalistic outlook, and extending it to the understanding of the processes of history (see MATERIALISM §3).

While materialism represents perhaps the most direct influence of science on philosophy, a less direct influence can be found in the revival of empiricism and the related position of positivism, where philosophers looked to science and scientific methods to understand how knowledge of the world is acquired, what form that knowledge takes and how far it can extend. As in the seventeenth and eighteenth centuries, this view rested on a sense that scientific inquiry was hugely successful, and so must form a model for all our cognitive endeavours. This model was inductivist: using observations and generalizations based on observations, science is able to uncover the law-governed causal relations between natural phenomena. According to this view, we are thereby able to reach an adequate understanding of the world, in the sense of an understanding that is perfectly satisfactory to science, without engaging in metaphysical speculation or attempting to transcend the boundaries of experience; no further kind of knowledge is possible for us, or even desirable, insofar as empirical science provides us with a fully adequate understanding of the world around us. As Mill makes clear, in adopting this sort of position, the empiricists and positivists of the nineteenth century saw themselves as returning to the earlier empiricist tradition of the seventeenth and eighteenth centuries:

> [T]he truth, on this much-debated question (concerning the sources of our knowledge) lies with the school of Locke and of Bentham. The nature and laws of Things in themselves, or of the hidden causes of the phenomena which are the objects of experience, appear to us radically inaccessible to the human faculties. We see no ground for believing that anything can be the object of our knowledge except our experience, and what can be inferred from our experience by the analogies of experience itself; nor that there is any idea, feeling, or power in the human mind, which, in order to account for it, requires that its origin should be inferred to any other source.
>
> (*Coleridge* 1840)

We have here a characteristic mix of empiricist and positivist themes, built around a renewed faith

in the methods and results of science as these were conceived of in the seventeenth and eighteenth centuries, together with a sharp awareness of the limits of scientific inquiry from a metaphysical perspective: metaphysical questions concerning the 'hidden causes of the phenomena' must be left unanswered, but in a way that leaves the adequacy of our investigations untouched. The sharp distinction between metaphysics and science that emerged in the seventeenth and eighteenth centuries can be seen to mark the positivism and empiricism of the second half of the nineteenth century, where in both periods the distinction was used to prioritize science over metaphysics, whereas in the early part of the century, the order of priority had been the opposite. (See BRENTANO, F.C.; COMTE, A.; MACH. E.; POSITIVISM IN THE SOCIAL SCIENCES.)

A third respect in which science came to influence philosophy from the 1840s onwards, in a manner that paralleled the influence it possessed in the seventeenth and eighteenth centuries, was the way in which respect for science (particularly physiology and psychology) led to a naturalistic view of the mind, as operating in accordance with processes and laws occurring in the natural causal order, with no place for any Kantian 'transcendental subject' outside this order. This has implications both for philosophy of mind and for epistemology, where the issue is to show how various mental capacities and forms of knowledge (such as innateness, a priori knowledge, intentionality or the normativity of thought) are compatible with this naturalistic picture, or (if they are not) how they can be explained away. This programme can be seen at its clearest and most thoroughgoing in Mill, and also in the work of Hermann von Helmholtz, Herbert SPENCER and William JAMES.

Thus the emergence of these three strands of thought – metaphysical materialism, empiricism and positivism, and naturalism – can be set against the dominant idealism of the first half of the century, and each can be seen as a revival of positions from the seventeenth and eighteenth centuries, shaped by a return to views of science and its relation to philosophy that first emerged in this early modern period. Nonetheless, there are important tensions between these strands that marked nineteenth-century debate, as had been the case when these positions first emerged. One tension was between metaphysical materialism on the one hand, and positivism on the other: for, from a positivist perspective, it appeared that materialism could not be justified, as it involved claims about the ultimate nature of reality that could not be supported on the basis of normal scientific inquiry, so transcending the epistemological limits that the positivists set themselves. Likewise, positivism encouraged an instrumentalist or conventionalist conception of scientific theories that threatened to lead to a kind of anti-realist constructivism concerning the natural world, which was also at odds with materialistic realism (see CONVENTIONALISM; DUHEM, P.M.M.; MACH, E.; POINCARÉ, J.H.). Another tension was between positivism and empiricism, where (as COMTE argued) positivism could make greater concessions to the rationalist and Kantian traditions than could an empiricist such as Mill, by accepting that scientific inquiry in fact involved observation shaped by some sort of prior theorizing. A further tension can be seen in the relation between empiricism and naturalism, for example in the way that Mill's empiricism led to phenomenalism, which holds that minds and experiences are all that exist; but this position seems to be at odds with his commitment to naturalism, which normally involves taking the human mind to be part of the natural world realistically conceived. Finally, while Comte sought to give the scientific understanding of society and historical development its own special status, the fact that this understanding was modelled on paradigms from the natural sciences inevitably threatened to make this form of social theory reductionistic (see POSITIVISM IN THE SOCIAL SCIENCES).

4 The re-emergence of idealism

As well as these internal tensions, the three strands of materialism, positivism and naturalism were also faced by counter-currents from idealism and the idealist tradition, which in different ways questioned the conception of science that these positions had taken up. So first, for example, the materialism of Büchner, Vogt and Moleschott was questioned by ENGELS, who was more sympathetic to the critique of mechanism offered by the *Naturphilosophen*, while opposing what he saw as their idealism. Engels argued that precisely because it was based around an early modern scientific paradigm, metaphysical materialism was outdated, with contemporary scientific developments such as electromagnetic field theory suggesting a less mechanistic and atomistic metaphysical picture (see also DIALECTICAL MATERIALISM). It was also argued by various Hegelians (such as Johann Bernard Stallo, an influence on EMERSON) that Hegel's conception of the dialectic and his emphasis on time and change made his position compatible with evolutionary theory, which in turn suggested less mechanistic ways of understanding the processes involved, as more than chance variation and natural selection. Similarly, in France Ravaisson adopted a more Romantic conception of nature based on the irreducibility of the higher mental faculties to

material processes, while the British psychologist James Ward was equally critical of mechanism. Moreover, while the Neo-Kantians were opposed to what they saw as the anti-scientific speculative metaphysics of Hegelian idealism, they nonetheless questioned how far human cognition could be reduced to natural processes, arguing that Kant's transcendental approach to epistemology is needed to provide a proper foundation for science (see COHEN, H.; NEO-KANTIANISM; RENOUVIER, C.B.).

Second, where positivism was committed to a unified conception of the scientific method, on the grounds that the human and the natural were continuous domains, those working in the Kantian tradition saw the need to reassert a fundamental division between the natural and the human sciences, and so questioned the assumption on which positivism was based. The most significant figure here is Wilhelm DILTHEY, who in the 1880s and beyond argued that human cultures required investigation not through classification and causal explanations, but from within, through lived experience, which was conceived of in historical terms, in contrast to the ahistorical paradigms of the natural sciences. Thus, according to Dilthey, while the positivists were right to hold that the natural sciences look for general laws, the *Geisteswissenschaften* have the different goal of seeking the meaning of particular human situations, thereby acquiring hermeneutic understanding rather than predictive control. (See also NATURALISM IN SOCIAL SCIENCE; NEO-KANTIANISM.)

Third, Mill's empiricist assumption that the scientific method was purely inductivist was challenged as a misrepresentation and oversimplification of actual scientific method by William WHEWELL, who offered a more Kantian picture, according to which ideas are prescribed to, and not derived from, sensations. He also claimed that positivism took its empiricist claims about the limits of inquiry too far, arguing that we must speculate about causes if we are to posit laws. Likewise, PEIRCE combined a commitment to the methods of science with a recognition of their metaphysical underpinnings, in a manner that led him to take the *Naturphilosophie* of Schelling and Hegel quite seriously, together with their anti-nominalist idealism.

Finally, as regards naturalism, some of the various schools of Neo-Kantianism in Germany stood against both the empiricist rejection of the a priori, and psychologism about the a priori, which seemed to subsume logic and epistemology under psychology. This non-naturalism was to have a decisive influence on twentieth-century philosophy through the anti-psychologism of FREGE. Opposition to naturalism can also be found in Royce's idealistic alternative (see ROYCE, J.) to James' naturalistic pragmatism and in the work of the British idealists, where T.H. GREEN in particular played Kant to Mill's Hume, accusing Mill and other empiricists of naivety in the face of Kant's recognition of Hume's lesson that naturalism leads to scepticism. Britain, along with other European countries, thus ended the nineteenth century with a revival of positions that had been dominant at the start of the century, but which had apparently been eclipsed by the 'return to the eighteenth century' that took place from the 1840s onwards. (See BERDIAEV, N.A.; BERGSON, H.-L.; BOSANQUET, B.; BRADLEY, F.H.; CROCE, B.; GENTILE, G.; MCTAGGART, J.M.E.)

Given the polarity that developed from the middle of the century onwards between idealism on the one hand, and various strands of materialism, positivism and naturalism on the other, it is not surprising that some thinkers sought ways of compromising between them. One route was to take up a kind of Kantian modesty, whereby positivism and naturalism are adopted with respect to the material world, but where this is said to place limits on our scientific knowledge, beyond which traditional metaphysical possibilities are left open and unresolvable by us. This allowed for a dualistic compromise between science and religion, of the sort favoured by Spencer, Thomas Huxley (who coined the term 'agnosticism'), William Hamilton, Leslie Stephens, Rudolph Virchow and Emil Du Bois-Raymond (who in a speech to the Berlin Academy of Science in 1880 famously delivered the verdict of 'Ignorabimus!' – 'we will never know!' – on the question of the origin of sensation and consciousness, amongst other 'world riddles'). To some, this humility appeared the highest wisdom; to others (such as Ernest HAECKEL) it appeared incoherent, obscure and in bad faith. Another strategy was to attempt to integrate idealism with these apparently competing positions: this led to the eclecticism of COUSIN (see ECLECTICISM), and also the similarly syncretic approaches of Taine, Renan, Cournot, Boutroux, LANGE and LOTZE, while many of the American pragmatists attempted to combine elements of idealism and naturalism, as in Dewey's attempt to reconcile Hegelianism and Darwinism in his early papers (an attempt he later abandoned, as he lost faith in the value of Hegel's idealism) (see DEWEY, J.).

However, even to some enthusiastic proponents of the revival of eighteenth-century paradigms in science and philosophy, it was still recognized that aspects of the social, ethical and religious picture offered by the idealists and Romantics were of value and should be retained. It was in these areas that Mill, for example, was keen to stress the true contribution of Coleridge and Carlyle and the school of German philosophy they represented, as a counterbalance to

the ahistoricism and abstract rationalising of the *philosophes*, the early utilitarians and the political radicals. Thus Mill, like many commentators since, sought to preserve the social and historical insights of the idealist tradition, but to divorce them from what he saw as their wrong-headed epistemological and metaphysical underpinnings.

5 The legacy of nineteenth-century philosophy

It can be seen therefore that the 'fight between the nineteenth century and the eighteenth' runs like a thread though the philosophical debates in the period we have been discussing (and where European ideas spread, a similar trajectory can be found in other countries: see LATIN AMERICA, PHILOSOPHY IN). Moreover, in an important sense, this fight continues even now, as Kantians and idealists question the positions of materialists, empiricists and positivists, in the light of scientific developments and disputes about the methodologies of science. While aspects of the nineteenth-century debate may perhaps be less strongly felt – such as the religious implications of these issues – the issues remain as central and pivotal to large areas of philosophy as previously, insofar as they concern not only our conception of the nature of reality, knowledge and the mind, but also of ethics, human freedom, society, historical understanding and politics. Many intellectual movements of the twentieth century – such as EXISTENTIALISM, phenomenology (see PHENOMENOLOGICAL MOVEMENT), CRITICAL THEORY and HERMENEUTICS – have underlying them this tension between 'naturalism' and various forms of 'anti-naturalism'. To understand our own preoccupations properly, we must understand the nineteenth-century debates that first reflected this tension.

ROBERT STERN

NISHIDA KITARŌ (1870–1945)

Considered Japan's first original modern philosopher, Nishida not only transmitted Western philosophical problems to his contemporaries but also used Buddhist philosophy and his own methods to subvert the basis of traditional dichotomies and propose novel integrations. His developmental philosophy began with the notion of unitary or pure experience before the split between subject and object. It developed to challenge other traditional opposites such as intuition and reflection, fact and value, art and morality, individual and universal, and relative and absolute. In its organic development, Nishida's philosophy reacted to critiques that it neglected the social dimension with political essays that sometimes aligned it with Japanese imperialism. It culminated in the 'logic of place', a form of thinking that would do justice to the contradictory world of human actions.

NOMINALISM

'Nominalism' refers to a reductionist approach to problems about the existence and nature of abstract entities; it thus stands opposed to Platonism and realism. Whereas the Platonist defends an ontological framework in which things like properties, kinds, relations, propositions, sets and states of affairs are taken to be primitive and irreducible, the nominalist denies the existence of abstract entities and typically seeks to show that discourse about abstract entities is analysable in terms of discourse about familiar concrete particulars.

In different periods, different issues have provided the focus for the debate between nominalists and Platonists. In the Middle Ages, the problem of universals was pivotal. Nominalists like Abelard and Ockham insisted that everything that exists is a particular. They argued that talk of universals is talk about certain linguistic expressions – those with generality of application – and they attempted to provide an account of the semantics of general terms rich enough to accommodate the view that universals are to be identified with them.

The classical empiricists followed medieval nominalists in being particularists, and they sought to identify the kinds of mental representations associated with general terms. Locke argued that these representations have a special content. He called them abstract ideas and claimed that they are formed by removing from ideas of particulars those features peculiar to the particulars in question. Berkeley and Hume, however, attacked Locke's

doctrine of abstraction and insisted that the ideas corresponding to general terms are ideas whose content is fully determinate and particular, but which the mind uses as proxies for other particular ideas of the same sort.

A wider range of issues has dominated recent ontological discussion, and concern over the existence and status of things like sets, propositions, events and states of affairs has come to be every bit as significant as concern over universals. Furthermore, the nature of the debate has changed. While there are philosophers who endorse a nominalist approach to all abstract entities, a more typical brand of nominalism is that which recognizes the existence of sets and attempts to reduce talk about other kinds of abstract entities to talk about set-theoretical structures whose ultimate constituents are concrete particulars.

NON-MONOTONIC LOGIC

A relation of inference is 'monotonic' if the addition of premises does not undermine previously reached conclusions; otherwise the relation is non-monotonic. Deductive inference, at least according to the canons of classical logic, is monotonic: if a conclusion is reached on the basis of a certain set of premises, then that conclusion still holds if more premises are added.

By contrast, everyday reasoning is mostly non-monotonic because it involves risk: we jump to conclusions from deductively insufficient premises. We know when it is worthwhile or even necessary (for example, in medical diagnosis) to take the risk. Yet we are also aware that such inference is 'defeasible' – that new information may undermine old conclusions. Various kinds of defeasible but remarkably successful inference have traditionally captured the attention of philosophers (theories of induction, Peirce's theory of abduction, inference to the best explanation, and so on). More recently logicians have begun to approach the phenomenon from a formal point of view. The result is a large body of theories at the interface of philosophy, logic and artificial intelligence.

NORMATIVITY

Something is said by philosophers to have 'normativity' when it entails that some action, attitude or mental state of some other kind is justified, an action one ought to do or a state one ought to be in. The philosophical area most distinctively concerned with normativity, almost by definition, is ethics. Arguably, every ethical concept or category involves normativity of some kind. One area of lively debate within ethics concerns the precise kind of normativity that is possessed by different ethical concepts: moral wrongness, virtue, wellbeing and so on. For example, if an action is wrong, does that entail that there is reason not to do it or just that there is reason to take a certain attitude (blame) towards those who do act in that way?

A second way in which ethics is concerned with normativity is in investigating how an ethical proposition's normative claim might be vindicated and considering whether it actually is vindicated. For example, if an action is morally wrong only if there is reason not to do it, can we then satisfactorily establish that any actions actually are wrong?

Yet a third kind of engagement with normativity concerns the very sources of normativity itself. An attempt to vindicate or debunk the implicit normativity of some specific ethical claim will ultimately face the question of what could support claims to normativity in general. Here we find a fertile debate between Humeans, who seek to ground practical normativity in instrumental rationality, and Kantians, who argue that practical reason necessarily includes formal constraints that extend beyond means/end coherence.

Philosophical discussion of normativity is by no means restricted to ethics, however. Epistemology has an irreducibly normative aspect, in so far as it is concerned with norms for belief. And the idea that meaning is implicitly normative has sparked some of the most exciting discussions in recent philosophy of language.

STEPHEN DARWALL

NOUS

Commonly translated as 'mind' or 'intellect', the Greek word *nous* is a key term in the philosophies of

Plato, Aristotle and Plotinus. What gives *nous* its special significance there is not primarily its dictionary meaning – other nouns in Greek can also signify the mind – but the value attributed to its activity and to the metaphysical status of things that are 'noetic' (intelligible and incorporeal) as distinct from being perceptible and corporeal. In Plato's later dialogues, and more systematically in Aristotle and Plotinus, *nous* is not only the highest activity of the human soul but also the divine and transcendent principle of cosmic order.

A.A. LONG

NOVALIS (GEORG PHILIPP FRIEDRICH VON HARDENBERG) (1772–1801)

Novalis (the name is a pseudonym adopted for his published writings) was, together with Friedrich Schlegel and Friedrich Schleiermacher, the leading philosophical thinker of 'early German Romanticism'. Until recently Novalis was regarded primarily as a poet and as the author of the novel *Heinrich von Ofterdingen*, who wrote some philosophical work in conjunction with his writings on natural science and on the political matters of his day. In the wake of the renewed philosophical interest in the philosophy of J.G. Fichte and other German idealist thinkers, there has been a reassessment of the writings of both Schlegel and Novalis. It is now apparent that, far from being, as most commentators present them, defenders of Fichte's 'subjective idealism', Novalis and Schlegel arrived at significant criticisms of Fichte's idealism and initiated an anti-foundationalist tendency in modern philosophy which still has significant resonances today.

NOZICK, ROBERT (1938–2002)

Although Robert Nozick published on an enormous range of topics, he is best known as a political philosopher, and especially for his powerful and entertaining statement of libertarianism. In *Anarchy, State, and Utopia* (1974), Nozick presents an image of a fully voluntary society, in which people cooperate only on terms which violate no one's rights.

Nozick's other major contributions to philosophy include an analysis of knowledge, and an accompanying response to scepticism, an account of personal identity and contributions to decision theory and the theory of rationality.

NYĀYA

See Nyāya-Vaiśeṣika

NYĀYA-VAIŚEṢIKA

The Nyāya school of philosophy developed out of the ancient Indian tradition of debate; its name, often translated as 'logic', relates to its original and primary concern with the method (*nyāya*) of proof. The fully fledged classical school presents its interests in a list of sixteen categories of debate, of which the first two are central: the means of valid cognition (perception, inference, analogy and verbal testimony) and the soteriologically relevant objects of valid cognition (self, body, senses, sense objects, cognition, and so on). The latter reflect an early philosophy of nature added to an original eristic-dialectic tradition. On the whole, classical Nyāya adopts, affirms and further develops, next to its epistemology and logic, the ontology of Vaiśeṣika. The soteriological relevance of the school is grounded in the claim that adequate knowledge of the sixteen categories, aided by contemplation, yogic exercises and philosophical debate, leads to release from rebirth. Vaiśeṣika, on the other hand, is a philosophy of nature most concerned with the comprehensive enumeration and identification of all distinct and irreducible world constituents, aiming to provide a real basis for all cognitive and linguistic acts. This endeavour for distinction (*viśeṣa*) may well account for the school's name. Into the atomistic and mechanistic worldview of Vaiśeṣika a soteriology and orthodox ethics are fitted, but not without tensions; still later the notion of a supreme god, whose function is at first mainly regulative but later expanded to the creation of the world, is introduced. In the classical period the Vaiśeṣika philosophy of nature, including the highly developed doctrine of causality, is cast into a rigorous system of six, later seven, categories (substance, quality, motion, universal, particularity, inherence, nonexistence). Nyāya epistemology increasingly influences that of Vaiśeṣika.

The interaction and mutual influences between Nyāya and Vaiśeṣika finally led to the formation of what may be styled a syncretistic school, called

Nyāya-Vaiśeṣika in modern scholarly publications. This step, facilitated by the common religious affiliation to Śaivism, occurs with Udayana (eleventh century), who commented on texts of both schools. Subsequently, numerous syncretistic manuals attained high popularity. Udayana also inaugurated the period of Navya-Nyāya, 'New Logic', which developed and refined sophisticated methods of philosophical analysis.

O

OBJECTIVITY

Introduction

Objectivity is one of the central concepts of metaphysics. Philosophers distinguish between objectivity and agreement: 'Ice-cream tastes nice' is not objective merely because there is widespread agreement that it is true. But if objectivity is not mere agreement, what is it? We often think that some sorts of claim are less objective than others, so that a different metaphysical account is required of each. For example, ethical claims are often held to be less objective than claims about the shapes of middle-sized physical objects: 'Murder is wrong' is held to be less objective than 'The table is square'. Philosophers disagree about how to capture intuitive differences in objectivity. Those known as non-cognitivists say that ethical claims are not, strictly speaking, even apt to be true or false; they do not record facts but, rather, express some desire or inclination on the part of the speaker. Others, dubbed subjectivists, say that ethical statements are in some sense about human desires or inclinations. Unlike the non-cognitivist, the subjectivist views ethical claims as truth-apt, but as being true in virtue of facts about human desires or inclinations. Some philosophers, referred to as anti-realists, disagree with both non-cognitivism and subjectivism, and attempt to find different ways of denying objectivity. Quietists, on the other hand, think that there are no interesting ways of distinguishing discourses in point of objective status.

1 Non-cognitivism and subjectivism

Intuitively, an ethical claim such as 'It is right to help those in distress' is less objective than a claim such as 'The table is square'. What does this intuition amount to? Non-cognitivists, such as Ayer, Blackburn and Gibbard, focus on the semantic function of the two claims. 'The table is square' has the function of asserting that a fact obtains in the world. If that fact obtains – if the table is square – then the claim is true; if not, it is false. Thus 'The table is square' is apt to be true or false: it is truth-apt. On the other hand, the non-cognitivist views 'It is right to help those in distress' as having a different semantic function: despite appearances, its function does not consist in asserting that a fact obtains in the world. It is not truth-apt; rather, it expresses an inclination, desire, or some other non-cognitive attitude of the speaker, in the same way that 'Hurrah!' or 'Boo!' merely expresses a favourable or unfavourable attitude. This is why some versions of non-cognitivism are called 'expressivism'. Ethical claims are less objective than claims like 'The table is square' since the latter are genuine truth-apt assertions, whereas the former are not. Non-cognitivists have viewed ethical claims as not objective in this sense for various reasons: because of widespread disagreement over moral matters, because moral facts seem 'queer' or 'odd', and because of the normative character of moral discourse.

There are problems with this way of capturing differences in objective status. Consider the inference:

1 If lying is wrong, then getting little brother to lie is wrong.
2 Lying is wrong.
3 Getting little brother to lie is wrong.

According to non-cognitivism, 'Lying is wrong' and 'Getting little brother to lie is wrong' are not truth-apt. But the inference is intuitively *valid*. And to say that an inference is valid is to say that the truth of the premises guarantees the truth of the conclusion. How can non-cognitivism explain the validity of the inference, given that it denies that (2) and (3) are even apt to be true? Relatedly, the non-cognitivist has a difficulty with (1). What sense can be made of a conditional whose antecedent and consequent are not truth-apt? Non-cognitivism has had difficulty in finding satisfactory answers to these questions.

Subjectivists take a different tack. They admit that 'It is right to help those in distress' is truth-apt, that its sincere utterance makes a genuine assertion. They thus avoid the sort of difficulty outlined above. But if an ethical claim genuinely asserts that a fact obtains, what sort of fact is it? According to the subjectivist, it is simply a fact about the person making the claim: when I say 'It is right to help those in distress' I am asserting that I desire to help them. Ethical claims are truth-apt, but the facts they assert to exist are facts about us, our desires, inclinations or subjective states. When I say 'It is right to help those in distress' I literally *mean* 'I desire to help those in distress'. This contrasts with claims like 'The table is square' which, though truth-apt, are not analysable in terms of facts about human subjectivity. In this sense, 'The table is square' is the more objective.

Subjectivism has difficulty in accounting for moral disagreement. If Jones says 'It is right to help those in distress' and Smith says 'It is wrong to help those in distress', they are disagreeing with each other, indeed contradicting one another. But if Jones means 'I (Jones) desire to help the unfortunate', whereas Smith means 'I (Smith) do not desire to help the unfortunate', there is no contradiction. So in what sense do they disagree?

Subjectivism may try to deal with this by focusing on a wider range of desires than those possessed by the individual who utters the statement. 'It is right to help those in distress' literally means 'Most people desire to help the unfortunate', so that its content is spelled out in terms of intersubjective agreement in desires. But this also faces problems. If it were true, it would be a contradiction to say that helping the unfortunate is right even though most people do not desire to do it. But it is not a contradiction, so even this wider subjectivist analysis must be flawed.

2 Anti-realist views of objectivity

Suppose we admit that two types of claim are truth-apt and yet do not have an anthropocentric subject matter. Do we have to view them as equally objective? Anti-realists, such as Wright and Dummett, think not. They try to show how differences in objectivity can be captured, without adopting either non-cognitivism or subjectivism. How can we distinguish between 'It is right to help those in distress' and 'The table is square' if we allow that both are truth-apt, and that neither is susceptible to a subjectivist analysis? One way would be to develop an analogue of the distinction between primary and secondary qualities, the *locus classicus* for which is Locke's *An Essay Concerning Human Understanding* (1689/90) (see PRIMARY–SECONDARY DISTINCTION). The standard example of a secondary quality is colour, while shape is usually held to be primary. What is involved in the claim that redness, for example, is a secondary quality? The idea is that there is a close relationship between facts about certain of our subjective states and statements like 'The mailbox is red'. In order to explain this relationship, we need to explain the notion of a best judgment. A judgment that an object is red is best when it is made in conditions that are optimally good for appraising whether or not the mailbox is red. These conditions could be specified very roughly as those that obtain out of doors, in the shade, at lunch time on a lightly overcast summer afternoon. To say that redness is a secondary quality is to say that our best judgments concerning the redness of objects determine the extension of the concept red. The extension of a concept is the class of things to which that concept can correctly be applied. So our best judgments about whether objects are red *determine* which class of objects the concept red can properly be applied to. In contrast, a primary quality like squareness is one whose extension is determined independently of facts about best judgments concerning squareness. Best judgments in this case merely detect an independently determined extension.

This way of saying how 'The mailbox is red' is less objective than 'The table is square' is different from the subjectivist analysis. To say that redness is secondary is not to say that 'The mailbox is red' literally means that 'If conditions were best, we would judge that the mailbox is red'. The claim is the weaker one, that our best judgments determine whether the mailbox falls in the extension of red. The proposal that redness is a secondary quality can therefore avoid the problems associated with subjectivism. And since it does not deny that 'The mailbox is red' is truth-apt, it avoids the problems associated with non-cognitivism. One way, then, to claim that ethical claims are less objective than claims like 'The table is square' is to argue that ethical qualities such as right, wrong, good and bad are secondary rather than primary.

According to the anti-realist, there can be more than one way of saying that one type of claim is less objective than another. Even if we cannot show that ethical qualities are secondary, there might be other ways of contrasting ethical claims with different claims. One way concerns what Wright calls 'objectivity of truth'. This notion of objectivity features prominently in Dummett's discussions of realism. To say that a class of statements exhibits objectivity of truth is to say that '[they] may be fully intelligible to us even though resolving their truth-values may defeat our cognitive powers (even when idealized)' (Wright in *Realism, Meaning and Truth*,

1986: 5). Their truth might be 'evidence-transcendent': they are determinately either true or false, even if we are in principle incapable of citing evidence for or against them. Take Goldbach's Conjecture (that every even number greater than two is the sum of two primes), or some claim about past happenings in some far distant galaxy. We understand these claims, but we are in principle incapable of resolving their truth-values. This gives us one way of claiming that mathematical or cosmological claims are more objective than claims about morals or comedy. There is little temptation to think that claims about the moral status of an action, or about the comic quality of a joke, may in principle transcend our best cognitive efforts. There are no difficulties akin to those affecting non-cognitivism and subjectivism: there is no denial of truth-aptitude, nor an assignment of an anthropocentric subject matter.

3 Objectivity of meaning and quietism

The main danger for the anti-realist story about objectivity comes from Wittgenstein's rule-following considerations (RFC). According to Wright, the RFC endanger the objectivity of meaning. This is the view that 'the meaning of a statement is a real constraint, to which we are bound . . . by contract, and to which verdicts about its truth-value may objectively conform, quite independently of our considered opinion on the matter' (Wright in *Realism, Meaning and Truth*, 1986: 5). The meaning of a statement imposes requirements on what counts as correct use of the statement, which determine what uses are correct and incorrect independently of any opinions we may subsequently form. The problem is that if the RFC destroy the idea that meanings are objective in this sense, they thereby threaten the various ways in which anti-realists attempt to draw comparisons concerning objectivity. For example, Wright believes that objectivity of truth implies objectivity of meaning. If the RFC force us to reject objectivity of meaning, they also force us to reject objectivity of truth. And if no discourses possess objectivity of truth, appealing to failure of objectivity of truth will be useless for drawing comparisons between discourses. Likewise, since the truth of any statement is a function of its meaning together with facts about the world, rejection of objectivity of meaning may entail that all qualities are secondary. The possibility of appealing to the primary–secondary distinction in order to draw a contrast will be endangered. In short, the RFC seem to threaten us with quietism about objectivity: the view that no principled, metaphysically interesting contrasts concerning objectivity can be drawn.

Anti-realists try to find ways of avoiding quietism, while retaining their interpretation of the RFC (Wright 1992: Ch. 6). Note that some philosophers, such as McDowell, think that there is a different way in which quietism about objectivity can open up. McDowell does not view the RFC as threatening the objectivity of meaning. So the relevance of the primary–secondary distinction and evidence-transcendent truth is not threatened in the direct manner envisaged in the previous paragraph. The distinctions the anti-realist wishes to draw can still be drawn: instead, what the RFC threaten is the idea that there is any interesting metaphysical *point* to be made by appealing to the distinctions in the first place. For example, it might be argued that the thought that the anti-realist primary–secondary distinction is of metaphysical relevance depends upon a conception of detecting or tracking facts that the RFC display to be untenable.

OBJECTUAL INTERPRETATION OF QUANTIFIERS

See QUANTIFIERS, SUBSTITUTIONAL AND OBJECTUAL

OBLIGATION, POLITICAL

The problem of political obligation has been one of the central concerns of political philosophy throughout the history of the subject. Political obligations are the moral obligations of citizens to support and comply with the requirements of their political authorities; and the problem of political obligation is that of understanding why (or if) citizens in various kinds of states are bound by such obligations. Most theorists conservatively assume that typical citizens in reasonably just states are in

fact bound by these obligations. They take the problem to be that of advancing an account of the ground(s) or justification(s) of political obligation that is consistent with affirming widespread obligations. Other theorists, however, anarchists prominent among them, do not accept the conservative assumption, leaving open the possibility that the best theory of political obligation may entail that few, if any, citizens in actual states have political obligations.

Much of the modern debate about political obligation consists of attempts either to defend or to move beyond the alleged defects of voluntarist theories. Voluntarists maintain that only our own voluntary acts (such as freely consenting to the authority of our governments) can bind us to obedience. Because actual political societies appear not to be voluntary associations, however, voluntarism seems unable to satisfy conservative theoretical ambitions. Some individualists turn as a result to nonvoluntarist theories of political obligation, attempting to ground obligations in the receipt by citizens of the benefits governments supply or in the moral quality of their political institutions. Others reject individualism altogether, defending communitarian theories that base our political obligations in our social and political roles or identities. Individualist anarchists reject instead the conservative ambitions of such theories, embracing a voluntarism which entails that most citizens simply have no political obligations.

A. JOHN SIMMONS

OBSERVATION

Observation is of undeniable importance in the empirical sciences. As the source of information from the world itself, observation has the role of both motivating and testing theories. Playing this role requires more than just opening our eyes and letting nature act upon us. It requires a careful attention to the information conveyed from the world so that an observation is meaningful. Scientific observation, in other words, is more than a physical act of sensation; it must be an epistemic act as well, with sufficient meaning and credibility to contribute to knowledge. A report of an observation, therefore, must be more than a 'Yes, I see'. It must describe just what is seen, 'I see that ______'.

This obligation to make observation relevant to theory suggests that there is an essential influence of background theories on the observations themselves. The theories we believe or wish to test tell us which observations to make. And describing the results of observations, that is, bringing out their informational content, will always be done in the language of the conceptual and theoretical system already in place. For these reasons, observation is said to be indelibly theory-laden. And the influence of background beliefs is even greater in cases of indirect observation where machines, like microscopes and particle detectors, are used to produce images of the objects of observation. Here, the reliability of the machines, and hence the credibility of the observation, must be based on a theoretical understanding of the interactions that are the links in the chain of information.

The influence of theory on observation is often seen as a threat to the objectivity of the process of testing and verification of theories, and hence of science in general. If theories are allowed to, indeed required to, select their own evidence and then to give meaning and credibility to the observations, the testing process seems to be unavoidably circular and self-serving. Observation that is theory-laden would guarantee success. But a look at the history of science shows that it does not. There are plenty of cases of observations that are used to disconfirm theories or at least undermine the theorist's confidence. Perhaps there is a kind of observation that is not influenced by scientific theory and can serve as a common, objective source of information to put theories to a rigorous and meaningful test. Or perhaps all scientific observation does bear the influence of background scientific theories, but not necessarily of the theory the observation is being used to test. This independence between the theories that support an observation and the theory for which the observation serves as evidence can break the circle in the process of testing and perhaps restore objectivity.

PETER KOSSO

OCCASIONALISM

Occasionalism is often thought of primarily as a rather desperate solution to the problem of mind–body interaction. Mind and body, it maintains, do not in fact causally affect each other at all; rather, it is God who causes bodily movements to occur 'on the occasion of' appropriate mental states (for example, volitions), and who causes mental states, such as sensations, on the occasion of the corresponding bodily states (for example, sensory stimulation).

This characterization, while correct in so far as it goes, is seriously incomplete. Occasionalists have seen the lack of real causal influence between mind and body as merely a special case of the more general truth that no two created beings ever causally affect each other. The one and only 'true

cause' is God, with created beings serving as the occasions for his causal and creative activity, but never as causes in their own right. (The one possible exception to this is that created agents may themselves bring about their own acts of will; this is necessary if they are to be in any sense free agents.) Occasionalism has always been held primarily for religious reasons, in order to give God the honour due to him as the Lord and ruler of the universe. It has never, however, been a majority view among philosophical theists.

OMNIPOTENCE

Traditional theism understands God to be the greatest being possible. According to the traditional conception, God possesses certain great-making properties or perfections, including necessary existence, omniscience, perfect goodness, and omnipotence. Philosophical reflection upon the notion of omnipotence raises many puzzles and apparent paradoxes. Could an omnipotent agent create a stone so massive that that agent could not move it? It might seem that however this question is answered, it turns out that, paradoxically, an omnipotent agent is not truly all-powerful. Could such an agent have the power to create or overturn necessary truths of logic and mathematics? Could an agent of this kind bring about or alter the past? Is the notion of an omnipotent agent other than God an intelligible one? Could two omnipotent agents exist at the same time? If there are states of affairs which an omnipotent agent is powerless to bring about, then how is the notion of omnipotence to be intelligibly defined? Yet if the notion of omnipotence is unintelligible, then traditional theism must be false. Another obstacle to traditional theism arises if it is impossible for God to be both perfectly good, and omnipotent. If an omnipotent God is powerless to do evil, then how can God be omnipotent?

JOSHUA HOFFMAN
GARY ROSENKRANTZ

OMNIPRESENCE

Western Scripture and religious experience find God present everywhere. Western thinkers make sense of this as their concepts of God dictate. Pantheists hold that God's being everywhere is every bit of matter's being a part or an aspect of God. Panentheists say that as God is the soul of the universe, God's being everywhere is his enlivening the whole universe as souls enliven bodies. But most theists reject these views, as most think that if God is perfect, he cannot be, be made of, or be embodied in, a flawed and material universe. Most theists think God intrinsically spaceless, that is, able to exist even if no space exists. Still, theists argue that God's knowledge of and power over creation make him present within it without occupying space or being embodied in matter. Some add that God is present in space not just by power and knowledge but in his very being. These try to explain a spaceless God's presence in space by likening it to the presence of a universal attribute like hardness. Hardness is not spread over hard surfaces, occupying them by having parts of itself in parts of them. Each part of a hard surface is hard. So all of hardness is in each part of a hard surface. So too, theists say, God is not spread out over space, filling parts of it with parts of himself. Rather, all of God is wholly present at each point in space and in each spatial thing.

BRIAN LEFTOW

OMNISCIENCE

The concept of omniscience has received great attention in the history of Western philosophy, principally because of its connections with the Western religious tradition, which views God as perfect in all respects, including as a knower. Omniscience has often been understood as knowledge of all true propositions, and though several objections to any simple propositional account of omniscience have been offered, many philosophers continue to endorse such an analysis. Advocates of divine omniscience have discussed many problems connected with both the extent of omniscience and the relation between this property and other alleged divine attributes. Three such issues are: Can an omniscient being properly be viewed as immutable? Would an omniscient being have knowledge of the future, and is such knowledge consistent with our future actions' being genuinely free? And should omniscience be thought of as including middle knowledge? That is, would an omniscient being know (but have no control over) what other free beings would in fact freely do if placed in various different situations?

THOMAS P. FLINT

ONTOLOGICAL ARGUMENT

See God, arguments for the existence of

ONTOLOGICAL COMMITMENT

A person may believe in the existence of God, or numbers or ghosts. Such beliefs may be asserted, perhaps in a theory. Assertions of the existence of specific entities or kinds of entities are the intuitive source of the notion of ontological commitment, for it is natural to think of a person who makes such an assertion as being 'committed' to an 'ontology' that includes such entities. So ontological commitment appears to be a *relation* that holds between persons or existence assertions (including theories), on the one hand, and specific entities or kinds of entities (or ontologies), on the other.

Ontological commitment is thus a very rich notion – one in which logical, metaphysical, linguistic and epistemic elements are intermingled. The main philosophical problem concerning commitment is whether there is a precise *criterion* for detecting commitments in accordance with intuition. It once seemed extremely important to find a criterion, for it promised to serve as a vital tool in the comparative assessment of theories. Many different criteria have been proposed and a variety of problems have beset these efforts.

Many important philosophical topics are closely connected with ontological commitment. These include: the nature of theories and their interpretation; interpretations of quantification; the nature of kinds; the question of the existence of merely possible entities; extensionality and intensionality; the general question of the nature of modality; and the significance of Occam's razor.

See also: Ontology; Quine, W.V.

MICHAEL JUBIEN

ONTOLOGY

The word 'ontology' is used to refer to philosophical investigation of existence, or being. Such investigation may be directed towards the concept of being, asking what 'being' means, or what it is for something to exist; it may also (or instead) be concerned with the questions 'What exists?', or 'What general sorts of thing are there?' It is common to speak of a philosopher's ontology, meaning the kinds of thing they take to exist, or the ontology of a theory, meaning the things that would have to exist for that theory to be true.

1 Existence and being

Since so many central debates of philosophy concern what types of things exist, scrutiny of the arguments used in them was bound to lead to investigation of the concept of existence and its logic. The most famous case of this kind is the Ontological Argument for the existence of God, and one of the most famous moves in the ensuing debate is Kant's claim that existence is not a property or predicate of existing things: 'cats exist' clearly tells us something, but it does not tell us of things which, in addition to being furry, feline and fleet of foot, have the further property of existence (see God, arguments for the existence of §§2–3; Existence).

This point, with which modern logic agrees, may teach us to formulate 'cats exist' as 'there are things which are cats' – in which it doesn't even look as if existence is functioning as a predicate. But many will think that this does not take us very far. It does not tell us how to describe the difference between a world in which cats exist and one in which they do not – other than by repeating the formula 'there are cats'; it will not advance our understanding of what it is for something to exist. Nor will it touch the somewhat dizzying question 'why does anything exist, rather than nothing?'.

Some philosophers, however, have taken an interest in existence or 'being' (as it tends to appear in their works or in the English translations), not because it appears as part of so many philosophical claims but because they take it for the central concept of philosophy. The most prominent examples are, in antiquity, Parmenides, and in the twentieth century, Martin Heidegger.

2 What is there?

In its characteristically philosophical form, this is not a question of detail (for example, are there mammoths?) but about the most general *kinds* of thing: are there universals, or only particulars? – is there mind or spirit, or is there only matter? – is there anything that exists without being in space and time? Thus the debate on the first of these questions between Platonists and nominalists, or on the second between idealists and materialists, might in each case be described as a difference of opinion about the correct ontology. So might the conflict over whether values are objective aspects of reality, or rather 'in the eye of the beholder', a matter of how we react to things rather than the things themselves (see Emotivism; Projectivism).

The questions 'What kinds of thing *ultimately* exist?' or '... *really* exist?' or '... exist *in themselves*?' are even more characteristically philosophical forms of the general ontological question.

To understand what usually lies behind these additional terms one needs a grasp of (1) the concept of a *reduction* and (2) the distinction between appearances and things-in-themselves.

Reduction. Berkeley famously claimed that material objects were just collections of 'ideas' (see Berkeley, G. §3). He did not mean that there were no chairs or tables, but that such things did not have a material, non-mental component; what really existed was all mental. There are spirits and their ideas, and we speak of chairs and so on when the latter occur in familiar, stable groupings. In modern terminology, he was claiming that material objects can be *reduced to* ideas. There are other common examples. In political discourse we often speak of what a particular state has done – but without having to suppose that there are such things as states distinct from the individual people who compose them. A once-popular thesis about the nature of mind was that there is nothing but bodies and their behaviour, and that words apparently naming mental states and happenings are just convenient ways of indicating types of behaviour (see Behaviourism, analytic; Reductionism in the philosophy of mind).

Things-in-themselves. We may distinguish between the way a thing appears, which will depend partly on the faculties and situation of whoever is perceiving it, and the way it is, independently of how anyone perceives it. The latter is the thing-in-itself. The terminology was made instantly famous by Kant, who argued that space and time (and therefore everything in space or time) were merely the way in which a non-spatiotemporal reality, things-in-themselves, appeared to humans (see Kant, I. §5).

3 Ontological commitment

The notion of ontological commitment has come to prominence in the second half of the twentieth century, mainly through the work of Quine (§5). On Quine's view the right guide to what exists is science, so that our best guide to what exists is our best current scientific theory: what exists is what acceptance of that theory commits us to.

But what is that? How do we determine what existents the acceptance of a given theory commits us to? Quine proposes a criterion, often summarized in the famous slogan 'to be is to be the value of a variable'. We are to see what types of thing are quantified over when the theory is stated in canonical form with predicate calculus as the underlying logic; the theory's ontological commitment is precisely to things of those types. This line of thought has given rise to much discussion (see Ontological commitment).

OPERA, AESTHETICS OF

Opera, which may be defined as a dramatic action set in large part to music, is an inherently unstable art form, more so than any other. It has been characteristic of its practitioners and critics to call it periodically to order, in idioms which vary but carry much the same message: the music exists to further the drama. This has often been taken to be a matter of settling the priority of two elements: music and text. But in fact three are involved: music, text and plot (or action).

Opera began very abruptly in northern Italy at the end of the sixteenth century, partly as the result of discussions about its possibility. To begin with, familiar Greek myths were employed, set in the vernacular, with simple accompaniments so that every word could be heard. This led to pre-eminence for the singers and for spectacle. After each wave of excess – vocal prowess, dance interludes, stilted plots and texts, then once again, in the nineteenth century, empty display, and later gargantuan orchestras – there was a movement of revolt. Philosophers rarely took part in these aesthetic disputes, most of them being uninterested in music, and possibly more relevantly, being uninterested in any subject which can only be studied in historical terms. But it is fruitless to think about opera apart from its manifestations; every great operatic composer makes his own treaty between the potentially warring elements, Wagner being the most passionate propagandist for his own conception. In the twentieth century the aesthetics of opera have become pluralistic, as has, to an unprecedented degree, the form itself. The perpetual danger is that opera should degenerate into entertainment, and it is always the same message

that recalls it to its original function – one which most spectators and listeners are happy to ignore: opera is a form of drama.

MICHAEL TANNER

OPERATIONALISM

'Operationalism', coined by the physicist Percy W. Bridgman, has come to designate a loosely connected body of similar but conflicting views about how scientific theories or concepts are connected to reality or observation via various measurement and other procedures. Examples of an operation would be the procedure of laying a standard yardstick along the edge of a surface to measure length or using psychometric tests to measure sexual orientation. In the 1920s through to the 1950s different versions of operationalism were produced by, amongst others: Bridgman, who was concerned with the ontology of basic units in physics; behaviourists such as E.C. Tolman and S.S. Stevens, who were concerned with the measurement of intervening variables or hypothetical constructs not accessible to direct observation, as well as B.F. Skinner, who sought to eliminate such nonobservables; and positivistic philosophers of science who were analysing the meaning of terms in scientific language. Conflation of their different operationalist philosophies has led to a great deal of nonsense about operational definition, methodology of observation and experiment, and the meaning of scientific concepts. Operationalist doctrines were most influential in the social sciences, and today the primary legacy is the practice of operationally defining abstract social science concepts as measurable variables.

FREDERICK SUPPE

ORDINAL LOGICS

By an ordinal logic is meant any uniform effective means of associating a logic (that is, an effectively generated formal system) with each effective ordinal representation. This notion was first introduced and studied by Alan Turing in 1939 as a means to overcome the incompleteness of sufficiently strong consistent formal systems, established by Kurt Gödel in 1931.

The first ordinal logic to consider, in view of Gödel's results, would be that obtained by iterating into the constructive transfinite the process of adjoining to each system the formal statement expressing its consistency. For that ordinal logic, Turing obtained a completeness result for the class of true statements of the form that all natural numbers have a given effectively decidable property. However, he also showed that any ordinal logic (such as this) which is strictly increasing with increasing ordinal representation cannot have the property of invariance: in general, different representations of the same ordinal will have different sets of theorems attached to them. This makes the choice of representation a crucial one, and without a clear rationale as to how that is to be made, the notion of ordinal logic becomes problematic for its intended use.

Research on ordinal logics lapsed until the late 1950s, when it was taken up again for more systematic development. Besides leading to improvements of Turing's results in various respects (both positive and negative), the newer research turned to restrictions of ordinal logics by an autonomy (or 'boot-strap') condition which limits the choice of ordinal representations admitted, by requiring their recognition as such in advance.

SOLOMON FEFERMAN

ORDINARY LANGUAGE PHILOSOPHY, SCHOOL OF

The label 'ordinary language philosophy' was more often used by the enemies than by the alleged practitioners of what it was intended to designate. It was supposed to identify a certain kind of philosophy that flourished, mainly in Britain and therein mainly in Oxford, for twenty years or so, roughly after 1945. Its enemies found it convenient to group the objects of their hostility under a single name, while the practitioners thus aimed at were more conscious of divergences among themselves, and of the actual paucity of shared philosophical doctrine; they might have admitted to being a 'group' perhaps, but scarcely a 'school'. The sharp hostility which this group aroused was of two quite different sorts. On the one hand, among certain (usually older) philosophers and more commonly among the serious-minded public, it was labelled as philistine, subversive, parochial and even deliberately trivial; on the other hand, some philosophers (for instance, Russell, Popper and Ayer), while ready enough to concede the importance in philosophy of language, saw a concern with ordinary language in particular as a silly aberration, or even as a perversion and betrayal of modern work in the subject.

How, then, did 'ordinary language' come in? It was partly a matter of style. Those taken to belong to the school were consciously hostile to the lofty, loose rhetoric of old-fashioned idealism; and to the

'deep' paradoxes and mystery-mongering of their continental contemporaries; but also to any kind of academic jargon and neologism, to technical terms and aspirations to 'scientific' professionalism. They preferred to use, not necessarily without wit or elegance, ordinary language. (Here G.E. Moore was an important predecessor.) Besides style, however, there were also relevant doctrines, though less generally shared. Wittgenstein, perhaps the most revered philosopher of the period, went so far as to suggest that philosophical problems in general actually consisted in, or arose from, distortions and misunderstandings of ordinary language, a 'clear view' of which would accomplish their dissolution; many agreed that there was some truth in this, though probably not the whole truth. Then it was widely held that ordinary language was inevitably fundamental to all our intellectual endeavours– it must be what one starts from, supplying the familiar background and terms in which technical sophistications have to be introduced and understood; it was therefore not to be neglected or carelessly handled. Again it was urged, notably by J.L. Austin, that our inherited everyday language is, at least in many areas, a long-evolved, complex and subtle instrument, careful scrutiny of which could be expected to provide at least a helpful beginning in the pursuit of philosophical clarity. It was probably this modest claim– overstated and even caricatured by its detractors – which was most frequently supposed to be the credo of ordinary language philosophers. It was important that Russell – like, indeed, Wittgenstein when composing his *Tractatus Logico-Philosophicus* (1922) – firmly believed, on the contrary, that ordinary language was the mere primitive, confused and confusing surface beneath which theorists were to seek the proper forms of both language and logic.

ORGANON

See Aristotle

ORIGEN (*c.*185–*c.*254)

An ascetic Christian, prodigious scholar and dedicated teacher, Origen devoted his life to exploring God's revelation. Much of his work takes the form of commentaries on Scripture. He argued that Scripture has three levels: the literal, the moral and the spiritual. The literal level veils the others, and we need God's help to find the divine mysteries behind the veil. His commentaries directly or indirectly influenced the practice of exegesis throughout the patristic period and the Middle Ages.

Origen used his spiritual exegesis, as well as arguments, concepts and models drawn from philosophy, to tackle the theological problems of his day: the compatibility of providence and freedom, the relation of the Father, Son and Holy Spirit to each other and to rational creatures, the problem of evil, and the origin and destiny of the soul. He is famous – or infamous – for arguing that the souls of angels, demons and human beings enjoyed a previous heavenly existence, but that they sinned and fell. God created the world to punish and remedy their faults.

ORTEGA Y GASSET, JOSÉ (1883–1955)

The Spanish philosopher Ortega borrowed themes from early twentieth-century German philosophy and applied them with new breadth and urgency to his own context. Calling his philosophy 'vital reason' or 'ratiovitalism', he employed it initially to deal with the problem of Spanish decadence and later with European cultural issues, such as abstract art and the mass revolt against moral and intellectual excellence. Vital reason is more a method for coping with concrete historical problems than a system of universal principles. But the more disciplined the method became, the deeper Ortega delved into Western history to solve the theoretical and practical dilemmas facing the twentieth century.

NELSON R. ORRINGER

OTHER MINDS

Introduction

It has traditionally been thought that the problem of other minds is epistemological: how is it that we know other people have thoughts, experiences and emotions? After all, we have no direct knowledge that this is so. We observe their behaviour and their bodies, not their thoughts, experiences and emotions. The task is seen as being to uncover the justification for our belief in other minds. It has also been thought that there is a conceptual problem: how can we manage to have any conception of mental states other than our own? It is noteworthy that there is as yet no standard view on either of these problems. One answer to the traditional

(epistemological) problem has been the analogical inference to other minds, appealing to the many similarities existing between ourselves and others. This answer, though it is no longer in general favour among philosophers, still has its defenders. Probably the favoured solution is to view other minds as logically on a par with the unobservable, theoretical entities of science. That other people have experiences, like us, is seen as the best explanation of their behaviour.

1 What generates the two problems of other minds?

The epistemological problem arises from two facts. We lack direct knowledge of the mental states of other people. We have such knowledge of at least some of our own mental states. Put the two claims together and we have the traditional problem of other minds. The relevant asymmetry, between our own case and that of others, turns on the question of direct knowledge, not observation. Being able to observe the mental states of others would not enable us to avoid the problem. What would be needed would be the ability to observe those mental states as the mental states of others. They would have to come labelled. The situation would only then be symmetrical. We would have the direct knowledge we lack.

The same asymmetry generates the conceptual problem. How can we have the concept of other people's experiences given that we have direct knowledge only of our own experiences, labelled as our own? Once again, the problem is not that we cannot observe the pains of others. What would be needed would be observing such pains as, indeed, the pains of others.

There has been comparatively little discussion of the conceptual problem, and no more will be said here about the conceptual problem of other minds, other than to note that solving it would not, other than controversially at best, remove the epistemological problem. That problem will be hereinafter the one under discussion.

2 Who has the epistemological problem?

The heroic way of avoiding the problem of other minds is to deny that the claimed asymmetry, between ourselves and others, holds. Some have done so by insisting that we have direct knowledge of the mental states of others, though this has generally been seen as implausible. However, there seems to be an important strand of thinking within feminist theory that would endorse this rejection of our asymmetry. Similarly, Continental European philosophy has commonly taken the view that other people are needed for us to acquire our own sense of ourselves as persons (see ALTERITY AND IDENTITY, POSTMODERN THEORIES OF). So our sense of others goes before our sense of self. That would seem to demand some capacity to know about others before one knows about oneself. The asymmetry would, presumably, be reversed, and the problem of other minds give way to the problem of our own minds.

Given that the asymmetry is accepted, and thus the traditional understanding of the problem of other minds, it has been almost a commonplace to believe that only a traditional dualist view of the mind produces a difficult problem of other minds (see DUALISM). Though generally theories of mind accept the asymmetry, not all are thought to have a difficult problem. Behaviourism (see BEHAVIOURISM, ANALYTIC) is a theory of mind that either is thought to have no problem at all, or, if it does, nevertheless has no difficulty in solving the problem. There is no special problem about knowing about the behaviour and behavioural dispositions of another.

Functionalism is another theory of mind that is thought not to have a difficult problem. Mental states are viewed as internal states of the organism, regulating its responses to its surroundings. The various mental states are differentiated by their various roles, and they have no other features relevant to their being the mental states they are (see FUNCTIONALISM). It is then claimed to be straightforward, faced with the behaviour of others, to infer that such internal states exist, in the appropriate relations to the behaviour. Eliminative materialists have been seen as not having any problem. If there are no minds, then there are no other minds, therefore there is no problem of other minds (see ELIMINATIVISM).

However, it has been argued that all theories of mind leave the other minds problem intact, and difficult. Theories of mind are, indeed, theories of mind, all minds, one's own and others. Given that they are to be true of all minds, including other minds, they cannot, it has been argued, be used to show that there are, indeed, other minds. It is unacceptable to argue that, say, functionalism is true, and then use this to solve the other minds problem, since it cannot be known to be true, to hold of minds in general, unless it holds of other minds.

How could that be known without the other minds problem having been, somehow, solved?

In conjunction with this line of argument, it has been pointed out that a theory of mind, embracing all minds, needs to embrace its propounder's mind as well as other minds. So a crucial part of the evidence (generally implicit) for a theory of mind will be that the theory fits the propounder's experience. That is the only way direct evidence in its favour can be obtained. So the propounder's experience is crucial. It has been argued that there is no escaping dependence on that experience and, as we shall see, any such dependence has been seen to be a fatal weakness, whenever it exists, in any would-be justification for belief in other minds.

3 The analogical inference to other minds

The traditional solution to the problem of other minds has been the analogical inference to other minds. Other people behave like me in similar circumstances and have the same physico-chemical composition. When I burn myself it hurts and I cry out and wince. When other people are burned they cry out and wince. I can thus infer that they are in pain too. More generally, others are very like me. I know I have beliefs, experiences and emotions. So I am entitled, given how like me they are, to infer that other people also have beliefs, experiences and emotions.

This traditional analogical inference to other minds is now generally incorporated in a hypothetic inference (scientific inference, inference to the best explanation) to other minds. That there are alternative hypotheses about others which have to be ruled out requires that the argument take the form of a hypothetic inference (see INFERENCE TO THE BEST EXPLANATION). But the appeal to one's own case, and to similarities, remains crucial in this analogical/hypothetic inference.

That, indeed, one's own case is crucial, gives rise to the classical, continuing objection to the analogical inference to other minds, that it is a generalization from one case. Such generalizations are almost invariably unsound. Though there have been attempts to put the analogical inference to other minds in a form that avoids this objection, it is generally accepted that such attempts have not succeeded.

However, its supporters argue that, even so, the analogical/hypothetic inference remains a sound inference, despite its dependence on one case. More than one case is needed where what is at issue is the question of a causal link between events. Where it can be known from one case that there is such a causal link, that one case will then be enough. It is claimed that the relevant causal link, involving mental states, can be known to hold from one's own case. Though it has traditionally been insisted that the relevant causal link is between mental states and behaviour, it has been urged that the relevant causal link needs to be between brain states and mental states if the analogical/hypothetic inference is to be defensible.

The other classical objection to the analogical inference to other minds has been that its conclusion was impossible to check, not just in fact, but in principle. This feature no longer seems to be seen as having any epistemological relevance.

4 Other minds as theoretical entities

This is probably, among Anglo-American philosophers, the favoured solution to the problem of other minds. The justification is in the form of a hypothetic inference. That others have mental states is hypothesized to account for how they behave. However, one proceeds purely from the outside. No evidence gathered from one's own case is used to support this hypothesis. The one case objection thought widely to be fatal to the analogical inference is, crucially, avoided, so it is widely believed.

It is generally considered that treating other minds in this way, as theoretical entities, will succeed if one has a functionalist (or some such) view of the mind. The two seem made for each other. However, the argument in §1, that no theory of mind has an advantage over any other in supporting belief in other minds, would, if successful, apply to this particular attempt to avoid dependence on one's own case.

It has been argued, conversely, that unless one enlists the help of a functionalist (or some such) theory of the mind, treating other minds as theoretical entities will not succeed. A traditional view of mental states, allowing that they have intrinsic content – in particular, phenomenal properties, such as the hurtfulness of pain (see QUALIA) – cannot be supported by this method. Treating the mental states of others as theoretical entities, it is argued, will not provide those states with the needed intrinsic properties. That content can only be filled in by an appeal to one's own case.

5 Criteria and other minds

Treating other minds as theoretical entities, though an alternative to the analogical inference, takes the form of a hypothetic inference. Criterialists, by contrast, have sought to avoid the one case problem by eschewing any form of inference. They have insisted that the link between behaviour and mental states is neither entailment (as in behaviourism) nor

an inductive inference. The link is claimed to be conceptual and such links are characterized as criterial. Behaviour is a criterion for the presence of mental states. It has been claimed by some that such a non-inferential connection is required if we are to have any concept of the experiences of others.

An example of such a claimed non-inferential link would be the claim that itching is conceptually linked to scratching, not merely contingently correlated. Our concept of itching is that it disposes one to scratch. It is further claimed that scratching is, thereby, evidence of itching, given that itching disposes one to scratch.

That there are such conceptual links has been widely argued and widely denied. That, if there are, they would provide a sufficient basis for belief in the mental states of other people has been, if anything, even more vigorously contested. The thrust of the attack on the use of criteria to support belief in other minds seems to be that such conceptual links fail to bridge the gap between observed behaviour and the unobserved inner states to which they are conceptually linked. If there is no entailment directly from the one to the other, and there is no appeal to some form of inductive inference, it is argued that we are left with the gap. The gap cannot be crossed by *fiat*, as it were.

One way of understanding what has been called the attitudinal approach to other minds, is to see it as going beyond other uses of criteria in insisting that our conception of other human figures is that they are souls, that they have experiences. That is how we perceive them. It is as immediate as that, preceding any belief. This criterial view seems, however, to inherit the criterial gap. However we conceive of reality, our conceptions might be mistaken. There are attitudes to things and people which, though more immediate and deeper than inferential belief, are, nevertheless, mistaken (racist and sexist attitudes might be given as instances).

6 Private language and other minds

It has been widely accepted that language is a public phenomenon. Some have insisted that it is essentially public. One way of understanding this claim is classically associated with Wittgenstein. A language that is necessarily private, that is, such that only one person can understand it, is (logically) impossible (see PRIVATE LANGUAGE ARGUMENT).

The connection with the problem of other minds has been controversial. However, it seems clear that the connection exists in the reason given for the impossibility of such a private language. That reason bears directly on the analogical inference to other minds.

A necessarily private language is claimed to be impossible because a language has to be, in principle, subject to checking by someone other than an individual user of the language. Generally, a user of the analogical inference to other minds is in breach of this principle. They have insisted that each of us knows what psychological terms mean (at any rate, some of them) from our own case and only from our own case. Their usage would not then be, in principle, one that could be checked for consistency. Functionalists, by contrast, make no such claim, and it should be noted that the connection from private language to other minds depends on the use of terms whose meaning would be private in the relevant sense. The connection is not directly to any particular argument to other minds.

The argument that a check is needed (in principle, so Robinson Crusoe is not in trouble) has generally been that, in its absence, no distinction can be made between its seeming to the language user that their usage is consistent, and its being so. They have only their impression to go on. The issue has been vigorously contested.

That a private language is impossible has not generally been used explicitly as an argument for other minds. Nor could it be. After all, it is only in principle that a language is to be checkable by other people. An important, though indirect role, however, could be seen as its supporting the criterialist insistence on the need for a conceptual connection between inner states and publicly observable states (see CRITERIA).

ALEC HYSLOP

OXFORD CALCULATORS

'Oxford Calculators' is a modern label for a group of thinkers at Oxford in the mid-fourteenth century, whose approach to problems was noticed in the immediately succeeding centuries because of their tendency to solve by 'calculations' all sorts of problems previously addressed by other methods. If for example the question was, what must a monk do to obey the precept of his abbot to pray night and day, a 'calculator' might immediately rephrase the question to ask whether there is a minimum time spent in prayer that would be sufficient to fulfil the abbot's precept, or a maximum time spent that would be insufficient to fulfil the precept. Or, if

grace was supposed to be both what enables a Christian to act meritoriously and a reward for having so acted, then a calculator might ask whether the degree of grace correlated with a meritorious act occurs at the moment of the meritorious act, before the act when the decision to act is being made, or after the act when the reward of increased grace is given. If a body was hot at one end but cold at the other, then a calculator might ask not whether it is to be labelled hot or cold, but *how* hot it is as a whole. Finally, if it was asked whether a heavy body acts as a whole or as the sum of its parts, then a calculator might take the case of a long thin rod falling through a tunnel pierced through the centre of the earth and attempt to calculate how the rod's velocity would decrease as parts of the rod passed the centre of the cosmos, if it acted as the sum of its parts.

Of these four questions, the last two were asked by Richard Swineshead, a mid-fourteenth century fellow of Merton College, Oxford, whose *Liber calculationum* (Book of Calculations) led to his being given the name 'Calculator'. By association with Richard Swineshead, other Oxford masters including Thomas Bradwardine, Richard Kilvington, William Heytesbury, Roger Swineshead and John Dumbleton have been labelled the 'Oxford Calculators'. Their work contains a distinctive combination of logical and quantitative techniques, which results from the fact that it was often utilized in disputations on sophismata (*de sophismatibus*). This same group of thinkers, with emphasis on their mathematical rather than logical work, has been called the 'Merton School', because many but not all of the Calculators were associated with Merton College, Oxford. Besides calculatory works, the same authors wrote works in which calculatory techniques are not so prominent, including commentaries on Aristotle, mathematical compendia and commentaries on Peter Lombard's *Sentences*.

EDITH DUDLEY SYLLA

P

PAINE, THOMAS (1737–1809)

Thomas Paine, born in Norfolk, England, spent his early years as an undistinguished artisan and, later, an excise officer. In 1774 he emigrated to America and settled in Philadelphia where he became a journalist and essayist. His *Common Sense* (1776) and sixteen essays on *The Crisis* (1776–83) were stunning examples of political propaganda and theorizing. In the late 1780s, in Europe, Paine wrote *The Rights of Man* (1791–2) and attacked the English political system. During the French Revolution he was a Girondin in the French Convention and wrote *The Age of Reason* (1794, 1796), savagely criticizing Christianity. He died in New York in 1809, an important figure in the sweep of the revolutionary politics in America, England, and France at the end of the eighteenth century.

BRUCE KUKLICK

PAINTING, AESTHETICS OF

Introduction

Why care about painting as an art? Does it offer to engage our aesthetic interest in ways that other art forms do not, or does it merely reproduce the aesthetic satisfactions they provide? Most paintings involve both marks on a surface, and something represented by those marks. Some attempts to say what is distinctive about painting concentrate on the former feature, understanding the art as an exploration of the two-dimensional picture plane. Others concentrate on the representational aspect, seeking to find something special about the things painting can represent, or the way in which it achieves this. The most promising approach acknowledges both aspects, and does so as essential elements in the *experience* we have of painting. If successful, this allows us to see painting as offering aesthetic values found elsewhere, but in a distinctive form. It also helps us to say something about a set of paintings we are otherwise in danger of ignoring – abstract works.

1 The question

What is there to value, aesthetically, in painting? At first glance, there are many things. Painting can, for instance, present us with beauty, express emotion or illuminate an abstract idea by embodying it in the representation of something concrete. These virtues are found in many other arts. This may seem to render it rather arbitrary to ask about the aesthetics of painting in particular. However, the inquiry makes perfect sense provided there is something distinctive in what painting has to offer. It may be that painting offers a unique combination of values, each of which can be found elsewhere; or it may be that some of what painting offers is found nowhere else. Each possibility provides an approach to our topic.

History provides instances of both approaches, sometimes within the work of a single author (see, for instance, Ruskin 1843–60). But either approach faces a further issue, that of just how circumscribed the realm of painting is taken to be. For example, the eighteenth-century theorist Lessing sought to describe values found in both pictorial art and sculpture, using these to draw aesthetic distinctions between the pair (which he called 'painting') and literature, above all poetry. Others, such as the American art critic Clement Greenberg, have hoped to distinguish the pictorial from the sculptural, in aesthetic terms. Even the pictorial itself presents difficulties: is it to include only painting proper, or some or all of the many other

ways in which art pictures can be made – fresco, drawing, etching and photography?

'Painting' is here taken to cover all the pictorial arts, bar photography. This approach presents special problems for aesthetics. We will ask whether there are things to value in these arts that are not found in other art forms. Why do we pursue this approach? One reason is the poverty of accounts of art in general, a poverty in part inherited from accounts of general artistic values. Another is that s/he who does not look, does not find. Since philosophical aesthetics stands in a two-way relationship with criticism, each able, at their best, to learn from the other, and since something parallel is true of criticism and ordinary aesthetic engagement, the worry is that if we do not look for what is special about painting from the viewpoint of philosophical aesthetics, an engagement with painting as it is actually practised might be impoverished both critically and on a day-to-day basis.

Not discussed here are two themes which have a certain topicality. One is the speculation that painting is dead, that it has run its course as an art form. The other is the radical overhaul in recent years of the self-conception of art history, as an academic discipline. The latter involves either a theme too large to tackle here – the idea that the aesthetic is itself an outmoded concept; or a theme that is irrelevant – the idea that art history should be concerned, at least in part, with non-aesthetic matters. The former does not undermine, but presupposes, our question. For if painting is dead, it is because it has explored to the full whatever aesthetic potential it has.

2 Some basic observations

It is unlikely that we could define 'painting', construed either narrowly or as broadly as is here required, except in terms that themselves import aesthetic considerations. So our inquiry cannot have a definition as a neutral starting point. However, there are some simple features common to all, or at least very many, of the items that concern us. Our topic is surfaces that have been marked by human hand, with the intention of stimulating the eye. The vast majority of these surfaces represent something. Matisse's *The Dance*, for instance, shows a group of circling dancers, holding hands and lost to the music. When surfaces are marked so as to represent in this way, they have two aspects. One, the *configurational* aspect, is a matter of what marks lie where. The other, *representational*, aspect is a matter of what the marks stand for, or represent.

This type of representation is found in many pictures which are not our concern, either because they involve methods of picture production we have here set aside (photography) or because they do not aspire to aesthetic interest (consider the illustrations in a car repair manual). There is a good deal of argument over how to characterize this representation (see DEPICTION). One approach will, however, be of particular relevance (see below). It sees pictorial representation as involving a special experience on the part of the viewers of the picture. In this experience, the precise nature of which is also controversial, we see the marks which make up the picture as organized in a special way, around the thought of whatever is represented: we see things in the marks, as for instance, the dancers in Matisse's canvas.

3 Answers stressing configuration

Although many paintings represent, it is at least not obvious that all do. One very natural way to understand abstract pictorial art is precisely as art that foregoes representation. So understood, abstract paintings will have a configurational aspect, since they are marked surfaces, but not a representational one. Anyone determined to stress the distinctiveness of painting as an art form, but also determined to give a central place to abstraction, is thus under pressure to concentrate on the configurational aspect of pictures. The clearest expression of these tendencies is in the work of Clement Greenberg.

Greenberg thought that painting had often succumbed to 'the confusion of the arts', importing values which properly belong in literature. The true purpose of painting is the exploration of the 'flatness' of the marked surface. What it uniquely offers is the opportunity to draw attention to the two-dimensional pattern of marks on the canvas, emphasizing their status as such, and exploring the opportunities for stimulation, commentary and surprise which such emphasis affords. Painting can do this while representing, but that representation is essentially irrelevant to its pursuit of this, its proper task. Greenberg saw the history of art in terms of the prominence or recession of this central preoccupation, citing Ingres' portraiture, for instance, as work which, while representational, stresses the picture plane. But it is only with abstraction that this tendency reaches its purest, and most elevated, form. For, while Greenberg allows that even most abstract paintings are not completely 'flat', they are the paintings where there is least to distract from the investigation of flatness. Abstract pictorial art is thus not just properly part of painting, but the purest embodiment of its ideals.

Greenberg's writing provides a crude but powerful formulation of themes of more general import. One is his emphasis on painting as a tradition, as a historically extended activity working through a

common problematic. Later exponents of the art draw on and react to the achievements and failures of their predecessors, and their work cannot be understood properly except as part of that ongoing, practically embodied, discussion. Another is Greenberg's stress on features of form, rather than content, as central to proper appreciation. The notion of form is very elastic, and in consequence 'formalism' names not one position but many (see FORMALISM IN ART). Not all of these positions exclude representation from the realm of the aesthetically significant. However, Greenberg is not alone in rejecting the relevance of representation; even if, in concentrating exclusively on painting, his claims apply far more narrowly than some formalist views.

Nonetheless, in the end Greenberg's position is unsatisfactory. A great part of the history of painting has been concerned with extending its powers of representation, or at least realistic representation. Indeed, it is possible to see these efforts as the fulcrum around which the history of Western pictorial art turns. Greenberg is forced to construe these efforts either as the pursuit of something other than painting altogether, or as misdirected fire which, somehow, nonetheless hits the real target, that of emphasis on the picture plane. He thus marginalizes what has some claim to be central, and which looks distorting. If there are other, better, ways to deal with abstraction, and less one-sided ways to identify distinctive pictorial values, they merit our attention.

4 Pure content

Positions geometrically opposed to that of Greenberg insist that the value of painting is entirely a matter of representation. Such views are the inheritors of the Aristotelian tradition that sees art as essentially *mimēsis*, or imitation (see MIMĒSIS). (ARISTOTLE distinguished these notions but the tradition following him did not.) If we reduce imitation to the bare power to represent something else, the tradition holds little promise. For even the crudest images or simplest combinations of words represent. Mere representing is thus neither special to pictorial art, nor in itself of aesthetic interest. However, perhaps we can progress further if we identify something distinctive about the representational content of pictures, something which might be developed by pictorial art.

At this point emerges a theme which has great prominence in the literature on painting, both philosophical and art historical. If there is something special about pictorial content, it lies in some kind of tie to vision. It is not just that pictures must be seen to be understood – that much is true of written language. It is that pictures represent things we see, and represent them in something like the way in which vision itself does. Something like this underlies the commonplace, developed by Ruskin into a principle of criticism, that pictorial art can sharpen our visual engagement with the world around us. Thus it is perhaps to painting that we owe the discovery that shadows can be coloured or our sense of the varieties of appearance which can be presented by clouds, trees or mountainsides (Ruskin 1843–60). And it is a closely related suggestion that painting might take visual experience as its explicit subject matter, capturing, for instance, the way that visual detail is distributed across the field of vision in response to shifts in focus and attention. But perhaps the most systematic development of ideas in this vein lies in Lessing's *Laocoon* (1766) (see LESSING, G.E.).

Lessing's attempt to separate painting from poetry begins with a feature they have in common: the aim of both is what he calls 'illusion'. The name may be misleading – Lessing's position is that each art aims to stimulate vivid sensory imaginings. The difference between the two arts stems from the signs each uses to represent. Since those of painting are simultaneously existing and spatially organized, they can 'express only objects whose wholes or parts coexist'. Poetry, in contrast, exploits signs which follow one another, and can thus 'express' only items made up of consecutive parts, that is, actions.

An important corollary is that painting can capture the aesthetic merit things have by virtue of the interrelations of their co-existing parts, i.e. 'material beauty'. Poetry is unable to imitate this, since our psychological limitations prevent us forming decent sensory images of the simultaneous on the basis of exposure to the successive. It is thus restricted to imitating the *effects* of material beauty, or beauty in movement, which Lessing calls 'charm'. Painting's task is to imitate material beauty. Lessing at least comes close to a stronger claim: that a painting's beauty – for him its main aesthetic merit – reduces to that of the thing represented.

There is much to question here. It is certainly false that a painting is only as beautiful as its represented object. There is more to a work, and to our awareness of it, than its representational aspect. We are aware of configurational properties too, and this alone makes it likely that the beauty of the whole comes apart from that of the represented object. Examples are easy to find. Bellini's *Doge Leonardo Loredan* is a work of an exquisite and delicate beauty; the represented Doge, while undeniably an impressive figure, does not have these qualities. Perhaps more damagingly, Lessing's prizing of beauty above all other painterly values seems, if only in the light of developments in art since his day, severely constricting.

These problems can be eased, if not entirely solved, without sacrificing the spirit of Lessing's view. We can explicitly deny that a painting is only as beautiful as its object, without thereby losing one of Lessing's key insights – that represented beauty can at least contribute to the beauty of the representation. And the narrow focus on beauty can be expanded to include other aesthetic qualities accessible to vision. Once we cease directly to link the aesthetic character of the work to that of its object, these need not even be positive qualities, as encountered face to face. We can allow that painting can succeed by virtue of capturing the repulsive and visually disturbing, as well as the erotic, the visually intoxicating and the sublime.

5 Painting and experience

The last section focused on construals of the Aristotelian formula, namely that art is mimēsis, which make do with a thin notion of imitation. A rather different set of views opens up if we draw on another of our basic observations outlined above. Perhaps the way pictures imitate is unique, essentially a matter of how they are experienced. This idea receives particularly clear expression in a view which there are some grounds for attributing to Lessing. As noted, we cannot put much weight on his talk of 'illusion' *per se*. However, he not only identifies illusion with vivid sensory imagining, he also seems to hold that imagining differs from sense perception only in terms of vivacity. If so, the most vivid acts of imagination will be indistinguishable, in terms of phenomenology, from acts of perception. *Illusionism* is the view that our experience of pictures is phenomenally identical with our experience of what they represent. The idea that this is painting's special gift, or at least its proper aim, has a very long history. Moreover, it links painting to vision in the strongest possible way. Can it also form the basis for a distinctive painterly aesthetic?

It cannot. The problem is not that many pictures do not generate illusion, in this sense. That is true, but shows the view to be false only as an account of pictorial representation, not as stating an ideal at which pictorial art should aim. Nor is the problem that this ideal has never been recognized by painting, or never attained. There are genuinely illusionistic moments in some pictorial art in the Western tradition. In the foreground of Caravaggio's *The Lute Player* (Metropolitan Museum, New York) lies a flute so realistic that one really does seem to be looking at polished wood glinting in the light. The problem is rather that too much great pictorial art does not even aspire to these effects. Consider the achievements of the twentieth century, the great Japanese woodcuts or medieval icon painting.

Nonetheless, illusionism does raise two problems of more general significance. First, if a painting's worth lies in its generating an experience as of its object, what does the picture have to offer that is not already on offer from the object itself? Of course, the latter may not be to hand, or may not even exist. But if the value of painting reduces to that of a convenient visual substitute, it is hard to understand the place it has held in Western culture. We might hope to circumvent this difficulty by saying that painting's value lies not in the nature of the experience it affords, but in the achievement involved in engendering that experience. It is nothing for a flute to present the appearance of one, but a considerable achievement for paint on canvas to do so.

However this, while appealing, runs into the second difficulty. It is very tempting to think that aesthetic value is peculiarly bound to experience. The most compelling form of this thought is that, if I experience two objects in exactly the same way, they cannot differ in value for me. Illusionism, as an aesthetic doctrine, precisely advocates such matching of experiences, of the painting and its object, as an ideal for pictorial art. But then painting and object cannot differ in value after all. Of course, illusionism can allow that the achieving of illusion may be manifest in experience of the painting, but only to the extent that the achievement is partial; the painting, by revealing its own presence, fails to present the appearance of the object. Thus we are forced into the paradox that, the greater the achievement, the less it is present. Art does not so much conceal, as annihilate, itself.

Both these problems hold more widely. The principle behind the second is at the heart of the problem of forgery, of how an original can be of differing aesthetic value from a perfect copy. And the difficulty of differentiating aesthetically between a painting and its object threatens many views which attempt to understand the value of painting in terms of its relations to vision. However, illusionism raises these difficulties in a particularly acute form. To make progress with them, we need a less extreme position.

6 Seeing-in and related phenomena

Illusionism is an accurate account of our experience of only a few pictures. Can an account which fits all pictorial representation fare better as the basis for an aesthetic of painting? Such an account would have to begin by recognizing the fact illusionism overlooks, namely that we are aware of both the representational and configurational aspects of pictures. As noted above (see §2), we experience the latter as organized around the thought of the former.

Schematic as this is, it already provides some help. By acknowledging the role of the configuration, we distance our experience of the picture from that of the represented object. We are thus able to explain at least how it is possible for the two to differ aesthetically. More than this, by stressing that we are aware of both aspects of the painting, we make room for the idea that it has a beauty which amounts neither to that of what is represented, nor to that of the marks considered merely as such, but to the way the one emerges from the other. This does indeed seem to be the case for many paintings – consider Bellini's *Doge Leonardo Loredan* again. This beauty is both important to painting and distinctively pictorial. For, while other art forms too can exhibit a beauty constituted by how what they represent emerges from the means by which it is so, only painting achieves this in the special experience by which pictorial content is grasped.

However, one lesson we took from discussing Lessing is that there must be more to pictorial art than beauty. When a painting is not beautiful, or when its beauty is only a part, perhaps a small part, of its aesthetic interest, what else is involved? We cannot here appeal, in the style of Aristotle, to the imitation itself, not even if we understand that as essentially involving our two-sided experience, seeing-in. For *every* picture sustains that experience, even those of no value. Moreover, we have no account of why that experience should, in itself, be of aesthetic significance. What, then, can we say?

We need to adopt a new strategy. Rather than searching for values found only in painting, or resorting to values found in exactly the same form elsewhere, we should try to understand painting as embodying more general values in a distinctive way. That distinctiveness is to stem from the way those values present themselves in pictorial experience. Seeing-in is thus not merely the means by which we grasp the representational content of a picture: it is also the conduit along which all pictorial value passes, and which gives the values thus accessed a distinctively pictorial shape. Seeing-in is not, now we have definitively rejected illusionism, face-to-face visual experience differently caused. But it is importantly related to ordinary vision. And it is so in such a way that what is aesthetically available in seeing-in is significantly linked to what is available in face-to-face visual contact with the world.

Thus, suppose that seeing things in the flesh not only presents us with certain individuals and their properties, but can also, on occasion, embody an affective response to those things. The skyscraper looks not merely grey and towering, but threatening, hostile. Perhaps seeing-in can similarly incorporate the affective, as when a De Chirico does not merely show strange buildings and alleys with long shadows, but captures a certain affective response to them, of poignant melancholy. If so, seeing-in offers not just a distinctively pictorial way to represent things, but the chance to represent them along with an affective response they merit. The response need not be one we would standardly have to such objects, and might even be one which, in real contact, no such object would ever elicit from us. Painting, then, seems to offer us the chance to explore how another might see the world and feel about it. It promises to initiate us into another sensibility.

This is something literature can do also, of course. What is distinctive about painting is that it does this in a specially visual form. It exploits the intermingling of percept and affect in everyday experience; and the way in which seeing-in is able to preserve such structural features of ordinary vision within what is, phenomenally, a quite different experience. It thereby allows the artist to speak to us by means, not of words and the images they can convey, but manipulated complexes of seeing and feeling.

This is, at most, only the start of an answer to our question. To flesh out our argument we would need to understand more about seeing-in, and in particular how it is able to deploy the resources of seeing face-to-face. We would need to understand those resources themselves far better, for instance, describing properly the role in ordinary vision of feeling. We would then need to spell out the significance provided by the possibility, in painting, of the artist's *controlling* our response, and the hold thus created for the notion of communication. We would need to explain how such control manifested itself in our experience. And we would need to expand our sense of the phenomena this structure allows for – is the above unique, or the model for a whole range of distinctively visual forms of more general artistic values which painting can offer? Having done all this, we would need to fit the values thus described into a plausible account of the tradition of painting, in something like Greenberg's sense of an historically extended, practically embodied, discussion between practitioners of the art (see §3).

We cannot do these things here. Although he does not frame them this way, the most serious attempt to tackle these questions is to be found in the work of Richard Wollheim (1987). The interested reader is directed there. Instead we may end by returning to just one of many matters outstanding – the question of abstract art. The above programme for constructing a pictorial aesthetic may seem already, even in this inchoate state, to ignore abstraction. For if pictorial values are distinctive through their involvement with seeing-in, and

seeing-in is the experience by which pictorial content is grasped, what are we to say of those pictures which, *prima facie*, have no such content? Wollheim has an answer. We do see things in abstract paintings. It is just that those things are highly schematic – not flutes, doges and dancers, but, for example, triangles intersecting with rectangles, simple shapes arranged in various planes. Perhaps this is not true of all abstract painting, but it is true of by far the greater part of it. Even Greenberg himself seems to concede as much. For it is hard to know what else to make of his acknowledgement that most abstract painting is not completely 'flat'. This tactic allows us at least to hope to treat most abstract painting as exploring the very same, perhaps multiple, values as the rest of the tradition. And if some pictures remain thereby excluded – Wollheim cites early Mondrian and Barnett Newman at his most distinctive – then perhaps that is a price that the aesthetic, once properly developed, can afford to pay.

PALEY, WILLIAM (1743–1805)

William Paley, theologian and moral philosopher, expressed and codified the views and arguments of orthodox Christianity and the conservative moral and political thought of eighteenth-century England. Paley says that his works form a unified system based on natural religion. Like others during this period, Paley thought that reason alone, unaided by revelation, would establish many Christian theses. He is confident that a scientific understanding of nature will support the claim that God is the author of nature. Paley belongs to the anti-deist tradition that holds that revelation supplements natural religion. The most important revelation is God's assurance of an afterlife in which the virtuous are rewarded and the vicious are punished. Natural and revealed religion, in turn, provide the foundation for morality. God's will determines what is right and his power to reward and punish us in the afterlife provide the moral sanctions. On the whole, Paley is concerned with sustaining Christian faith, and ensuring that people know what their duties are and do them.

PANENTHEISM

See God, concepts of

PANPSYCHISM

Panpsychism is the thesis that physical nature is composed of individuals each of which is to some degree sentient. It is somewhat akin to hylozoism, but in place of the thesis of the pervasiveness of life in nature substitutes the pervasiveness of sentience, experience or, in a broad sense, consciousness. There are two distinct grounds on which panpsychism has been based. Some see it as the best explanation of the emergence of consciousness in the universe to say that it is, in fact, universally present, and that the high-level consciousness of humans and animals is the product of special patterns of that low-level consciousness or feeling which is universally present. The other ground on which panpsychism is argued for is that ordinary knowledge of the physical world is only of its structure and sensory effects on us, and that the most likely inner content which fills out this structure and produces these experiences is a system of patterns of sentient experience of a low level.

T.L.S. SPRIGGE

PANTHEISM

Pantheism contrasts with monotheism (there is one God), polytheism (there are many gods), deism (God created the world in such a way that it is capable of existing and operating on its own, which God then allows it to do) and panentheism (in God there is a primordial and unchanging nature, and a consequent nature that changes and develops). Etymologically, pantheism is the view that Deity and Cosmos are identical. Theologically, it embraces divine immanence while rejecting divine transcendence. If atheism is the denial that anything

is divine, pantheism is not atheism; if atheism is the claim that there is no Creator, Providence, transcendent Deity, or personal God, pantheism is atheistic.

Spinoza, perhaps the paradigm figure for pantheism, was described by some as 'a God-intoxicated man' and by others as an atheist. On his account, only *God or Nature* exists, a single, necessarily existing substance whose modes and qualities exhaust reality. Conceivable equally properly as physical or as mental, God or Nature is no proper object of worship, creates nothing, grants freedom to none, hears no prayer, and does not act in history. Personal immortality, on Spinoza's view, not only does not occur, but is logically impossible. It is one thing to value nature so highly that one calls it a divinity, another to believe in God in any monotheistic sense.

This much said, it must be admitted that 'pantheism' is not easy to define precisely. As conceived here, pantheism need not be a variety of materialism, and if it is materialistic it includes a high view of the worth of matter. Yet 'pantheism' has served as a term of abuse, and as another term for 'atheism' and 'materialism' and 'deism', terms bearing quite different senses.

KEITH E. YANDELL

PARACELSUS (PHILIPPUS AUREOLUS THEOPHRASTUS BOMBASTUS VON HOHENHEIM) (1493–1541)

Paracelsus (pseudonym of Theophrastus Bombastus von Hohenheim) was an itinerant Swiss surgeon and physician who formulated a new philosophy of medicine based on a combination of chemistry, Neoplatonism and the occult, all within a Christian framework. His works, usually in German rather than Latin, were mostly published after his death. His importance for medical practice lay in his insistence on observation and experiment, and his use of chemical methods for preparing drugs. He rejected Galen's explanation of disease as an imbalance of humours, along with the traditional doctrine of the four elements. He saw the human being as a microcosm that reflected the structure and elements of the macrocosm, thus presenting a unified view of human beings and a universe in which everything was interconnected and full of vital powers. Paracelsian chemical medicine was very popular in the late sixteenth and seventeenth centuries, largely due to its presentation as part of a general theory.

PARACONSISTENT LOGIC

A logic is paraconsistent if it does not validate the principle that from a pair of contradictory sentences, A and ∼A, everything follows, as most orthodox logics do. If a theory has a paraconsistent underlying logic, it may be inconsistent without being trivial (that is, entailing everything). Sustained work in formal paraconsistent logics started in the early 1960s. A major motivating thought was that there are important, naturally occurring, inconsistent but non-trivial theories. Some logicians have gone further and claimed that some of these theories may be true. By the mid-1970s, details of the semantics and proof-theories of many paraconsistent logics were well understood. More recent research has focused on the applications of these logics and on their philosophical underpinnings and implications.

GRAHAM PRIEST

PARADIGMS

See Kuhn, Thomas Samuel (§4)

PARADOXES, EPISTEMIC

The four primary epistemic paradoxes are the lottery, preface, knowability, and surprise examination paradoxes. The lottery paradox begins by imagining a fair lottery with a thousand tickets in it. Each ticket is so unlikely to win that we are justified in believing that it will lose. So we can infer that no ticket will win. Yet we know that some ticket will win. In the preface paradox, authors are justified in believing everything in their books. Some preface their book by claiming that, given human frailty, they are sure that errors remain. But then they justifiably believe both that everything in the book is true, and that something in it is false.

The knowability paradox results from accepting that some truths are not known, and that any truth is knowable. Since the first claim is a truth, it must be knowable. From these claims it follows that it is possible that there is some particular truth that is known to be true and known not to be true.

The final paradox concerns an announcement of a surprise test next week. A Friday test, since it can be predicted on Thursday evening, will not be a surprise yet, if the test cannot be on Friday, it cannot be on Thursday either. For if it has not been given by Wednesday night, and it cannot be a surprise on Friday, it will not be a surprise on Thursday. Similar reasoning rules out all other days of the week as well; hence, no surprise test can occur next week. On Wednesday, the teacher gives a test, and the students are taken completely by surprise.

PARADOXES OF SET AND PROPERTY

Emerging around 1900, the paradoxes of set and property have greatly influenced logic and generated a vast literature. A distinction due to Ramsey in 1926 separates them into two categories: the logical paradoxes and the semantic paradoxes. The logical paradoxes use notions such as set or cardinal number, while the semantic paradoxes employ semantic concepts such as truth or definability. Both often involve self-reference.

The best-known logical paradox is Russell's paradox concerning the set *S* of all sets *x* such that *x* is not a member of *x*. Russell's paradox asks: is *S* a member of itself? A moment's reflection shows that *S* is a member of itself if and only if *S* is not a member of itself – a contradiction.

Russell found this paradox by analysing the paradox of the largest cardinal. The set *U* of all sets has the largest cardinal number, since every set is a subset of *U*. But there is a cardinal number greater than that of any given set *M*, namely the cardinal of the power set, or set of all subsets, of *M*. Thus the cardinal of the power set of *U* is greater than that of *U*, a contradiction. (The paradox of the largest ordinal, is similar in structure.)

Among the semantic paradoxes, the best known is the liar paradox, found by the ancient Greeks. A man says that he is lying. Is what he says true or false? Again, either conclusion leads to its opposite. Although this paradox was debated in medieval Europe, its modern interest stems from Russell, who placed it in the context of a whole series of paradoxes, including his own.

GREGORY H. MOORE

PARETO PRINCIPLE

A social state is said to be Pareto-efficient when there is no feasible alternative to it in which at least one individual is better off while no individual is worse off. The Pareto principle tells us to move from Pareto-inefficient to Pareto-efficient states. Suppose a large basket of fruit is shared among a group in some way or another – one apple, two peaches, a dozen cherries each, for instance. If the fruit can be exchanged so that at least some people get more enjoyment from what they have, and no one gets less, the Pareto principle instructs us to do so; indeed, it instructs us to carry on exchanging until no more improvements of this kind are possible.

DAVID MILLER

PARMENIDES (early to mid 5th century BC)

Parmenides of Elea, a revolutionary and enigmatic Greek philosophical poet, was the earliest defender of Eleatic metaphysics. He argued for the essential homogeneity and changelessness of being, rejecting as spurious the world's apparent variation over space and time. His one poem, whose first half largely survives, opens with the allegory of an intellectual journey by which Parmenides has succeeded in standing back from the empirical world. He learns, from the mouth of an unnamed goddess, a dramatically new perspective on being. The goddess's disquisition, which fills the remainder of the poem, is divided into two parts; the Way of Truth and the Way of Seeming.

The Way of Truth is the earliest known passage of sustained argument in Western philosophy. First a purportedly exhaustive choice is offered between two 'paths' – that of being, and that of not-being. Next the not-being path is closed off: the predicate expression '. . . is not' could never be supplied with a subject, since only that-which-is can be spoken of and thought of. Nor, on pain of self-contradiction, can a third path be entertained, one which would conflate being with not-being – despite the fact that just such a path is implicit in the ordinary human acceptance of an empirical world bearing a variety of shifting predicates. All references, open or covert, to not-being must be outlawed. Only '. . . is' (or perhaps '. . . is . . .') can be coherently said of anything.

The next move is to seek the characteristics of that-which-is. The total exclusion of not-being leaves us with something radically unlike the empirical world. It must lack generation, destruction, change, distinct parts, movement and an asymmetric shape, all of which would require some not-being to occur. That-which-is must, in short, be a changeless and undifferentiated sphere.

In the second part of the poem the goddess offers a cosmology – a physical explanation of the very world which the first half of the poem has banished as incoherent. This is based on a pair of ultimate principles or elements, the one light and fiery, the other heavy and dark. It is presented as conveying the 'opinions of mortals'. It is deceitful, but the goddess nevertheless recommends learning it, 'so that no opinion of mortals may outstrip you'.

The motive for the radical split between the two halves of the poem has been much debated in modern times. In antiquity the Way of Truth was taken by some as a challenge to the notion of change, which physics must answer, by others as the statement of a profound metaphysical truth, while the Way of Seeming was widely treated as in some sense Parmenides' own bona fide physical system.

DAVID SEDLEY

PASCAL, BLAISE (1623–62)

Blaise Pascal was a mathematical prodigy who numbered among his early achievements an essay on conic sections and the invention of a calculating machine. In his early twenties he engaged in the vigorous European debate about the vacuum, undertaking, or causing to be undertaken, a series of experiments which helped to refute the traditional view that nature abhors a vacuum and setting out clearly the methodology of the new science. In 1646 he came under the influence of Jansenism; this he seems to have rejected for a short time in the early 1650s, but he then underwent a profound spiritual experience which transformed his life and drew him into close association with leading Jansenists, with whom he collaborated in producing the polemical *Lettres provinciales* (1656–7). At the same time he planned to write an apology for the Christian religion, but ill-health so affected his final years that this only survives in the fragmentary form of the *Pensées* (1670). He made significant contributions to mathematics, especially in the fields of geometry, number theory and probability theory, and he also helped to describe the *'esprit géométrique'* which characterized the new science of the 1650s. He argued that geometry was superior to logic in that it could provide not only demonstrative procedures but also axioms from which to work; and he set down appropriate rules of argument. His religious writings were published shortly after his death; many attempts have been made to reconstruct the apology which they encapsulate. It seems most likely that this would have fallen into two parts, the first setting out the wretchedness of humans without God, the second demonstrating the truth of Christianity and the felicity of the religious life. Humans are portrayed in Augustinian terms as corrupt, vapid creatures, prey to their passions and the delusions of imagination; but they are also shown to possess greatness through their reason and self-awareness, which can bring them to recognize that Christianity alone has represented their predicament accurately, and that they should turn to religion, even if initially they lack the instinctive faith which is the hallmark of the saved. In the 'wager' fragment, Pascal employs his mathematical insights to revivify an old apologetic argument (that it is wiser to bet on God existing rather than on his not existing) and to link it to an existential imperative (that we all are obliged to choose between these alternatives). The adroit interplay between scepticism, rationalism and faith of the first part is succeeded by a second part which argues the veracity of Christianity from Biblical interpretation, prophecies and miracles. Pascal concedes that this cannot carry absolute conviction; but he insists that the rejection of such arguments is caused not by man's rational powers but by his corrupt passions. Pascal's *Pensées* are written for the most part in terse aphoristic form; he aspired to a style that was so accessible that the reader would believe he was experiencing as his own the thoughts that he read. Although Pascal said at the end of his life that he considered his mathematical pursuits a quite separate enterprise from his religious writings, a common epistemology can be found in both, together with a scientific outlook which Pascal saw as superior to the philosophical alternatives of his day.

IAN MACLEAN

PASSMORE, JOHN ARTHUR (1914–)

John Passmore was born in New South Wales and studied at the University of Sydney. He taught there before moving to Otago in New Zealand and then to the Australian National University. He is perhaps best known for *A Hundred Years of Philosophy* which has been widely recognized as a major feat of philosophical scholarship. He has contributed widely to topics in the history of philosophy, philosophy of education, philosophy of science and philosophy of the environment. He is one of the pioneers of what has come to be called applied philosophy.

FRANK JACKSON

PATERNALISM

Restriction of people's liberty of action is paternalistic when it is imposed for the good of those whose liberty is restricted and against their will. The argument in favour of paternalism is that, if one can prevent people from harming themselves, there is no reason not to do so. Versions of the ethical creed of liberalism tend to oppose paternalism. One argument is that as a practical matter the policy of permitting paternalism tends to do more harm than good in the long run, or at least less good than a strict refusal to countenance paternalism would achieve. Another argument appeals to a right of autonomy which paternalism is held to violate whether or not its consequences on the whole are undesirable. Paternalist advocacy can be 'hard' or 'soft'; soft paternalism is the doctrine that paternalism can only be justifiable when the individual action that is being restricted was not chosen in a substantially voluntary way.

PATRISTIC PHILOSOPHY

Early Christian writers used terminology and ideas drawn from Graeco-Roman philosophical literature in their theological writings, and some early Christians also engaged in more formal philosophical reflection. The term 'patristic philosophy' covers all of these activities by the 'fathers' (*patres*) of the Church. The literature of nascent Christianity thus contains many concepts drawn from Graeco-Roman philosophy, and this early use of classical ideas by prominent Christians provided an authoritative sanction for subsequent philosophical discussion and elaboration.

Early Christians were drawn to philosophy for many reasons. Philosophy held a pre-eminent place in the culture of the late Hellenistic and Roman world. Its schools provided training in logical rigour, systematic accounts of the cosmos and directions on how to lead a good and happy life. While philosophical movements of the period, such as Neoplatonism or Stoicism, varied widely in their doctrines, most presented accounts of reality that included some representation of the divine. These rationally articulated accounts established the theological and ethical discourse of Graeco-Roman culture. As such, philosophy had a natural appeal to Hellenistic Jewish and early Christian thinkers. It provided a ready language in which to refine ideas about the God of the ancient Hebrew scriptures, and to elaborate the trinitarian God of Christianity. It also helped to bring conceptual coherence to the ideas found in the scriptures of both religions. Finally, it provided the common intellectual discourse that those communities required in order to present their central tenets to the majority culture of the Roman empire.

To a considerable extent, the notion of 'philosophy' suggested to the ancients a way of life as much as an intellectual discipline. This too drew Christians to the teachings of the philosophers. While there were doctrines and prescriptions of behaviour specific to the major schools, philosophers in general tended to advocate an ethically reflective and usually rather ascetic life, one which conjoined intellectual with moral discipline. This ethical austerity was prized by early Christians as an allied phenomenon within Graeco-Roman culture to which they could appeal in debates about the character of their new movement. The tacit validation that philosophy offered to the Christian movement was thus multifaceted, and, while it was sometimes thought to be associated with unacceptable aspects of pagan religious culture, philosophy provided some educated Christians with a subtle social warrant for their new life and beliefs.

It should be noted that ancient Christianity was itself a complex movement. Like Graeco-Roman philosophy, Christianity included a broad spectrum of beliefs and practices. Thus those early Christians who developed their beliefs with reference to philosophy endorsed a wide range of metaphysical and ethical doctrines, ranging from materialism to extreme transcendentalism, from asceticism to spiritual libertinism. Yet, while diversity is evident, it is also true that the Christian movement came to develop a rough set of central beliefs and some early forms of community organization associated with those beliefs. This incipient 'orthodoxy' came to value some sorts of philosophy, especially Platonism, which seemed best suited to its theological agenda. This tacit alliance with Platonism was fraught with ambiguity and uncertainty, and it was never a reciprocal relationship. Nonetheless, in the second and third centuries a type of Christian philosophical theology emerged which owed much to the Platonic school and became increasingly dominant among orthodox Christian authors. It was this trajectory that defined the character of patristic philosophy.

Early Christian thought had its origins in Hellenistic Judaism, and its initial character was defined by the dominant patterns of that tradition. This early phase extended through the first half of the second century AD, as Christianity began to define its distinctive themes associated with the nature and historical mission of Jesus Christ. Throughout the second century, Christianity became increasingly a movement made up of gentile converts; some of these new members had educations that had included philosophy and a few were even trained as philosophers. Thus Christian thought began to show increased contact with the Graeco-Roman philosophical schools, a trend no doubt reinforced by the critical need for Christians – as a proscribed religious minority – to defend their theology, ritual practices and ethics in the face of cultural and legal hostility.

This so-called 'age of the apologists' lasted throughout the second and third centuries, until Christianity began to enjoy toleration early in the fourth century. However, it would be a mistake to consider Christian philosophical thought in that period as primarily directed towards the surrounding pagan society. In many respects philosophy, as the intellectual discourse of Graeco-Roman culture, offered gentile Christians a means to clarify, articulate and assimilate the tenets of their new faith. This process of intellectual appropriation appears to have been of considerable personal importance to many Graeco-Roman converts. Christian philosophical theology helped them to recover ideas familiar from their school training and to find unfamiliar concepts defended with the rigour much prized within Graeco-Roman culture.

After Christianity became a licit religion in the fourth century, philosophical activity among

Christians expanded. The task of theological self-articulation became increasingly significant as Christianity grew in the fourth and fifth centuries towards majority status within the Empire, with imperial support. In this later period the range and sophistication of Christian thought increased significantly, due in part to the influence of pagan Neoplatonism, a movement that included a number of the finest philosophers active since the classical period of Plato and Aristotle. Later patristic philosophy had a defining influence upon medieval Christian thought through such figures as Augustine and Dionysius the pseudo-Areopagite, establishing both the conceptual foundations and the authoritative warrant for the scholasticism of the Latin West and Greek East.

PEIRCE, CHARLES SANDERS (1839–1914)

Peirce was an American philosopher, probably best known as the founder of pragmatism and for his influence upon later pragmatists such as William James and John Dewey. Personal and professional difficulties interfered with his attempts to publish a statement of his overall philosophical position, but, as the texts have become more accessible, it has become clear that he was a much more wide-ranging and important thinker than his popular reputation suggests.

He claimed that his pragmatism was the philosophical outlook of an experimentalist, of someone with experience of laboratory work. His account of science was vigorously anti-Cartesian: Descartes was criticized for requiring an unreal 'pretend' doubt, and for adopting an individualist approach to knowledge which was at odds with scientific practice. 'Inquiry' is a cooperative activity, whereby fallible investigators progress towards the truth, replacing real doubts by settled beliefs which may subsequently be revised. In 'The Fixation of Belief' (1877), he compared different methods for carrying out inquiries, arguing that only the 'method of science' can be self-consciously adopted. This method makes the 'realist' assumption that there are real objects, existing independently of us, whose nature will be discovered if we investigate them for long enough and well enough.

Peirce's 'pragmatist principle' was a rule for clarifying concepts and hypotheses that guide scientific investigations. In the spirit of laboratory practice, we can completely clarify the content of a hypothesis by listing the experiential consequences we would expect our actions to have if it were true: if an object is fragile, and we were to drop it, we would probably see it break. If this is correct, propositions of a priori metaphysics are meaningless. Peirce applied his principle to explain truth in terms of the eventual agreement of responsible inquirers: a proposition is true if it would be accepted eventually by anyone who inquired into it. His detailed investigations of inductive reasoning and statistical inference attempted to explain how this convergence of opinion was achieved.

Taken together with his important contributions to formal logic and the foundations of mathematics, this verificationism encouraged early readers to interpret Peirce's work as an anticipation of twentieth-century logical positivism. The interpretation is supported by the fact that he tried to ground his logic in a systematic account of meaning and reference. Much of his most original work concerned semiotic, the general theory of signs, which provided a novel framework for understanding of language, thought and all other kinds of representation. Peirce hoped to show that his views about science, truth and pragmatism were all consequences of his semiotic. Doubts about the positivistic reading emerge, however, when we note his insistence that pragmatism could be plausible only to someone who accepted a distinctive form of metaphysical realism. And his later attempts to defend his views of science and meaning bring to the surface views which would be unacceptable to an anti-metaphysical empiricist.

From the beginning, Peirce was a systematic philosopher whose work on logic was an attempt to correct and develop Kant's philosophical vision. When his views were set out in systematic order, positions came to the surface which, he held, were required by his work on logic. These include the theory of categories which had long provided the foundations for his work on signs: all elements of reality, thought and experience can be classified into simple monadic phenomena, dyadic relations and triadic relations. Peirce called these Firstness, Secondness and Thirdness. He also spoke of them as quality, reaction and mediation, and he insisted that the error of various forms of empiricism and nominalism was the denial that mediation (or Thirdness) was an irreducible element of our experience. Peirce's 'synechism' insisted on the importance for philosophy and science of hypotheses involving continuity, which he identified as 'ultimate mediation'. This emphasis upon continuities in thought and nature was supposed to ground his realism. Furthermore, his epistemological work came to

focus increasingly upon the requirements for rational self-control, for our ability to control our inquiries in accordance with norms whose validity we can acknowledge. This required a theory of norms which would explain our attachment to the search for truth and fill out the details of that concept. After 1900, Peirce began to develop such an account, claiming that logic must be grounded in ethics and aesthetics.

Although pragmatism eliminated a priori speculation about the nature of reality, it need not rule out metaphysics that uses the scientific method. From the 1880s, Peirce looked for a system of scientific metaphysics that would fill important gaps in his defence of the method of science. This led to the development of an evolutionary cosmology, an account of how the world of existent objects and scientific laws evolved out of a chaos of possibilities through an evolutionary process. His 'tychism' insisted that chance was an ineliminable component of reality, but he argued that the universe was becoming more governed by laws or habits through time. Rejecting both physicalism and dualism, he defended what he called a form of 'Objective Idealism': matter was said to be a form of 'effete mind'.

CHRISTOPHER HOOKWAY

PELAGIANISM

Pelagius, a Christian layman, was active around AD 400. The thesis chiefly associated with his name is that (i) human beings have it in their own power to avoid sin and achieve righteousness. Critics objected that this derogates from human dependence on the grace of God. Pelagius did not deny that the power to avoid sin is itself a gift of God, an *enabling* grace; but he was understood to deny the need for *cooperative* grace, divine aid in using the power rightly, or at least to assert that (ii) such aid is a reward for human effort, and so not an act of grace. Later thinkers who held that God's aid, though not a reward, goes only to those who do make an effort, were accused of believing that (iii) there is no need of *prevenient* grace in causing the effort in the first place. So Pelagianism is a tendency to magnify human powers: its defenders saw it as a (frightening) challenge to humans, its detractors as an insult to God. It was hard without Pelagianism to find a place for free will, or with it for original sin.

PERCEPTION

Introduction

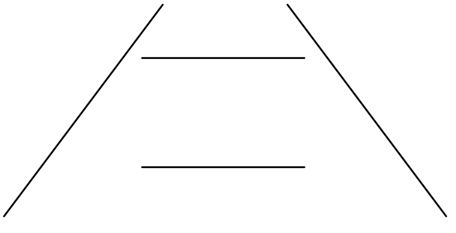
Sense perception is the use of our senses to acquire information about the world around us and to become acquainted with objects, events, and their features. Traditionally, there are taken to be five senses: sight, touch, hearing, smell and taste.

Philosophical debate about perception is ancient. Much debate focuses on the contrast between appearance and reality. We can misperceive objects and be misled about their nature, as well as perceive them to be the way that they are: you could misperceive the shape of the page before you, for example. Also, on occasion, it may seem to us as if we are perceiving, when we do not perceive at all, but only suffer hallucinations.

Illusions and hallucinations present problems for a theory of knowledge: if our senses can mislead us, how are we to know that things are as they appear, unless we already know that our senses are presenting things as they are? But the concern in the study of perception is primarily to explain how we can both perceive and misperceive how things are in the world around us. Some philosophers have answered this by supposing that our perception of material objects is mediated by an awareness of mind-dependent entities or qualities: typically called sense-data, ideas or impressions. These intermediaries allegedly act as surrogates or representatives for external objects: when they represent aright, we perceive; when they mislead, we misperceive.

An alternative is to suppose that perceiving is analogous to belief or judgment: just as judgment or belief can be true or false, so states of being may be correct or incorrect. This approach seeks to avoid intermediary objects between the perceiver and the external objects of perception while still taking proper account of the possibility of illusion and hallucination. Both responses contrast with that of philosophers who deny that illusions and hallucinations have anything to tell us about the nature of perceiving proper, and hold to a form of naïve, or direct, realism.

The account of perception one favours has a bearing on one's views of other aspects of the mind and world: the nature and existence of secondary qualities, such as colours and tastes; the possibility of giving an account of the mind as part of a purely physical, natural world; how one should answer



scepticism concerning our knowledge of the external world.

1 Perception, objects, appearance and illusion

We perceive objects, features of objects, and events: I can see a lilac bush, notice the texture of a piece of velvet, hear an explosion. We can also perceive facts, that things are a certain way: I may see that there are three empty coffee cups in my office, or smell that the milk has gone off. When we perceive things, they appear a certain way to us and we come to acquire knowledge concerning them, but one can also perceive facts without perceiving any object in particular: scanning the horizon you might see that there is nothing at all in your vicinity; you have perceived that something is the case, but there is no object that you have seen.

Objects can vary in their appearance: how something looks to you depends on the point of view from which you see it; how things appear to you depends on the conditions under which you perceive, for example whether the lighting is good; and they depend on your powers of perception, for example, how much you can smell or taste may depend on whether you have a cold. The same object may appear differently to different observers. Furthermore, you may not only perceive different aspects of an object from others, you may misperceive it, or suffer an illusion concerning it.

One misperceives something where one does perceive it, but it appears differently to one from how it really is. Misperceptions occur in different ways: one might mistake a clump of grass for a rabbit; in odd lighting the walls of a room may look peach, even when they are really off-white; one may be subject to illusions due to disease. Other examples of illusion happen in normal conditions of perception to all perceivers. Here is one example, common in psychology text books, called the Ponzo illusion:

The two horizontal lines are in fact the same length, even though the top one looks longer. Psychologists and neuroscientists are adept at causing other illusions as well: in one alarming example, subjects are made to feel as if their noses are growing back into their heads.

It is also possible to bring about hallucinations. These are cases in which it seems to subjects as if they are really seeing or feeling something, when in fact they are seeing nothing at all. They are most commonly caused by psychological disturbance, but it is also possible to bring them about through appropriate stimulation of the brain: apparent sightings of lights, called phosphenes, arise from stimulation of the visual cortex.

Philosophers tend to draw the same conclusion from all these of kinds of example: it is possible for things to seem a certain way to you, even if they are not that way. Just as one cannot determine from the object of perception how things appear to a perceiver, so one cannot determine from how things appear to a perceiver what the object of perception is, or even whether there is such an object. This implies that an account of perception involves two distinct tasks: on the one hand, it needs to explain what perceptual experience is, the state of mind when things sensorily appear a certain way to one; on the other, it needs to explain what it is for such an experience to be a genuine perception of some object, as opposed to a mere illusion or hallucination.

Under what conditions is a perceptual experience the perception of a given object? One might think that how things appear must match the object in some respect, but there seems to be no particular respect in which I must perceive correctly in order to perceive an object: one can misperceive the colour, shape, location, taste, smell or texture of things. Even if how things appear to me matches perfectly the scene before me, I do not necessarily perceive the scene: if a scientist has induced a visual hallucination in me as of an orange, merely placing an orange in front of my blindfolded eyes will not thereby make me see it. In response to such examples of veridical hallucination, some philosophers have suggested that one can perceive an object only if it causes one's perception of it. This condition is not sufficient by itself to distinguish veridical hallucinations from perceptions: the orange before my blindfolded eyes may be resting on the switch of the machine inducing the hallucination. Various attempts have been made to refine the causal condition in order to give a complete account of the difference between hallucination and perception, but none as yet seems entirely satisfactory in explaining our ability to discern a difference between the two.

The basic task for any theory of perceptual experience is to explain the following. In perceiving, things appear to you a certain way. For example, when you see a red patch on the wall in front of you, it can look to you as if there is a red patch there. In such a case, where you perceive things to be the way that they are, a case of veridical perception, a description of what your experience is like – that is, of how things appear to you – is also a true description of what you can see. In this case, it seems as if a description of your experience is also a description of the things in the world which you can perceive. However, you could have an experience just the same for you even if you were having an illusion, and not seeing something red, or a hallucination and not seeing anything at all. In either case, you would be inclined to give the same description of your experience as in the veridical case, but in neither would the description be true of what was before you in the world, since no red patch would be there. So, how can it be correct to describe your experience in terms of objects in the world, when the description can be true when applied to your experience, but false when applied to the world? This is the question which lies behind the so-called argument from illusion, and different theories of perception answer it in different ways.

2 Sense-datum theories of perception

Some philosophers claim that we are not aware, or anyway not immediately aware, of objects in the world around us, but only of things which depend on the mind for their existence and nature. Suppose that there is no red patch on the wall before me, but that a neuroscientist has so affected my brain that it looks to me as if there is a red patch before me. One might think that it could only appear to me as if some red thing was before me, if there actually was something red of which I was aware. Since the neuroscientist can give me the hallucination just by affecting my brain in the right way, it seems as if bringing about the experience was sufficient for there to be such a red patch for me to be aware of. At least in the case of hallucination, I would be aware of an entity which depended for its existence on my awareness of it; philosophers have used the term sense-datum, for such entities (see SENSE-DATA).

The hallucination could be just the same for me as the experience I would have were I actually looking at a physical red patch on the wall. And the neuroscientist could be bringing this about by stimulating my visual cortex in just the way it would be stimulated if I was looking at the wall. So, it may seem plausible to suppose that my hallucination is of the same sort as the experience I would have were I genuinely perceiving. If the hallucinatory experience is of a kind which involves being aware of a sense-datum, then even in the case of veridical perception I will be aware of such a mind-dependent entity. Hence we arrive at the sense-datum theory of experience: that we are aware of mind-dependent entities in all perceptual experience.

One criticism of this line of thought is that it involves a form of fallacious reasoning. If I believe that there are fifteen elephants in the next room, it does not follow that there are fifteen elephants in the next room which I believe to be there – after all, my belief may be false – so it would be a mistake to accept the latter claim on the basis of the former. Critics suggest that in the above claim, when one moves from the uncontroversial claim that it looks to me as if there is a red patch before me, to the conclusion that there is a red patch which looks to be before me, just such a mistake in reasoning has been made. However defenders of sense-datum theories of perception would agree that the claim does not follow simply as a matter of logic. Rather, they claim that we can only offer an adequate explanation of what experience is like, if we accept that the latter claim is true when the former is.

How good an explanation of what experience is like does this offer? The theory is committed to claiming that when things appear a certain way to you, then some sense-datum actually is that way. Suppose it seems to you as if there is a rabbit in the field before one; is one then aware of some mind-dependent bunny? In order to resist this conclusion, the sense-datum theorist needs to restrict the range of qualities which can strictly be apparent to us; namely to only those which sense-data might plausibly be thought to have. In the case of vision, this has traditionally been restricted to colour, shape and size (there is some dispute over whether visual data are located in a two-dimensional or a three-dimensional visual space). Hence, it could not strictly look (in the relevant sense) as if a rabbit was before one, only as if something rabbit-shaped were there.

If appearances are to be accounted for solely in terms of mind-dependent entities, what connection holds between experience and the objects of perception, such as the rabbit? Representative theories of perception typically hold that material objects are the indirect or mediate objects of perception in virtue of reliably causing our experiences of sense-data. I can perceive the rabbit in front of me, because the visual experience of something rabbit-shaped is caused by the rabbit. One traditional objection to representative theories of perception is that they lead to scepticism concerning the external world (see SCEPTICISM). In response, some philosophers adopt an alternative view of the connection between objects of perception and experience, taking physical objects to be no

more than constructions out of mind-dependent entities or experiences (see Phenomenalism; Idealism §2). Few philosophers find this position acceptable. Must a sense-datum theorist choose between scepticism and idealism? One may deny that representative theories of perception introduce any special sceptical problems. Whether this is so or not depends on whether sense-data should be thought of as cutting us off from the external world, as a veil of perception, rather than providing us with our only access to the world.

Are the metaphysical implications of the sense-datum theory acceptable? It requires us to accept that in addition to such familiar things as rocks and chairs, and discoveries such as black holes and neutrinos, there are mind-dependent objects which come into and go out of existence as each person has an experience. Philosophers have complained that such entities must be inherently mysterious and that we can discern no readily agreed method of determining when one has the same or a different sense-datum. Furthermore, their existence would rule out explaining how the mind comes to be part of a purely physical, natural world (see Materialism in the philosophy of mind).

Some philosophers have thought that these worries would be lessened if we eliminated inner objects of awareness, and appealed instead simply to ways in which one senses. According to this view, when one senses a red patch, one should not suppose that there has to be some object, a patch which one senses, but rather that one senses redly or in a red manner. One might compare this to singing a lullaby: we need not suppose that there is some thing which the singer sings, rather that they have sung in a certain, quieting manner. Where the sense-datum theory posits inner objects and qualities in order to explain the character of perceptual experience, this adverbial theory of experience appeals just to the manners or qualities of experiencing, sometimes called qualia, subjective qualities or sensational properties of experience.

Critics of the adverbial theories have pointed out that we make a distinction between on the one hand sensing a red square and green triangle, and on the other sensing a green square and a red triangle. It is difficult to explain this difference without appealing to the idea that an object is both square and red in the one case, and square and green in the other. There seems to be no sense in which a state of mind, or a sensing, could literally be square or round.

There is a further objection to be made from how we describe our experiences which applies to both adverbial and sense-datum theories. Various philosophers have denied that introspection of one's visual experience reveals the mind-independent objects which one perceives, and the features which one perceives them to have. Our experience of the world is diaphanous or transparent: introspection of it takes one through to the objects and features in the world, much as in staring at a pane of glass head on, one's attention is taken through to what lies beyond it.

The objection has two aspects to it. On the one hand, there is a negative claim that no introspective evidence can be found for the existence of mind dependent objects or qualities. Since such things are introduced as just that of which one is aware, one might expect that if there are such things, they should just be obvious through introspection. It is not evident that this negative claim is correct: opponents have claimed that evidence for them is provided by the example of after-images; or in the way that a nearer object can fill up more of one's field of view than a more distant object, even though both look the same size; or in our awareness of the fact that we are seeing the shape of an object rather than feeling it. Whether such examples really do demonstrate the existence of subjective qualities is a matter of further dispute, but the other element of the transparency objection can be made without having to settle that matter. It points out a positive element of the character of experience, as revealed through introspection, namely that mind-independent objects of perception are there in your experience. An account of experience which appeals solely to sense-data and qualia would not predict that these mind-independent elements should be part of our experience.

One reply to this is to deny that perceptual experiences really do have this diaphanous character. So, it has been suggested that we describe an experience as of a cube merely in order to indicate the typical cause of such experiences. But this suggestion is implausible. We do sometimes pick out experiences indirectly by reference to their typical cause, as when we call a certain distinctive pain a nettle sting. In this case it does not seem as if the term nettle should be applied directly to a description of what the pain is like. But one may claim that visual experience is not like that, the description of experience as of something red, or square or hard involves applying those terms directly to what one senses.

The objection is more pressing against adverbial theories than sense-datum theories. We describe our visual and tactual experiences in terms of shape properties. As noted above, a sense-datum theorist will dispute whether we also have to describe our experiences in terms of other qualities which could only be the properties of material objects. However, even if the objection is not decisive, it has been influential as a motivation for an alternative account of perceptual experience.

3 Intentional theories of perception

If it can seem to me that there is a red patch on the wall in front of me, when nothing physical is there, and the patch in question seems to be a part of the objective world external to me, then perhaps it can seem to me as if something is so, without anything actually having to be that way. We are all familiar with the fact that one may think that something is the case, when it is not so, as when one believes England will win the World Cup at cricket, and one may think about something, even if it does not really exist, as when small children hope that Santa Claus will visit their house that night. An intentional theory of perception claims that the case of perceptual experience is parallel to these examples: perceptual experience is intentional, and allows for incorrectness in its content, and non-existence of its objects in just the way that beliefs and judgments may do so (see INTENTIONALITY).

When it appears to one as if there is a red patch before one, one's experience represents the world as containing such a patch. If there is no patch there, how one's experience represents the world to be is incorrect, and one's experience is illusory. If the object of one's experience is non-existent, like Santa Claus, then one's experience is a hallucination and not the perception of anything. For the intentional approach, experience is ascribed a representational content which may be correct or incorrect; the experience is veridical, or illusory depending on the correctness of this content. What the experience is like for the subject, as revealed through reflection on it, is to be explained by that representational content. It is important to note that the intentional theory does not introduce the representational content of experience as an object of awareness, in the way that a sense-datum theory introduces sense-data as objects of awareness. Rather, the intentional theory claims that, in the case of perceiving, the objects of awareness are the mind-independent objects that one perceives, and which one's experience represents to be present. In the case of hallucination, there are no objects of awareness, but the character of experience is just the same as that in the case of perception: in both cases it is to be explained by the representational content that the experience has. So the intentional theory offers an account not of the objects of awareness, but rather the mode in which we can be aware of objects in the world.

How like belief could experience be? One view is that we can identify experience with the acquiring of beliefs, or with dispositions to acquire belief. A problem for this suggestion is that one can disbelieve one's senses. Those familiar with the Ponzo illusion do not believe that the top line is longer, but it still looks longer. A belief theory of experience may respond to this example by claiming that you are still disposed to believe that the top line is longer, it is just that other beliefs you have prevent you forming that belief. But this response is not really satisfactory: when you look at the illusion, you then have an experience which could have led to the belief in question; no mere disposition to acquire a belief can be identified with an occurrent state of mind which interacts with one's other mental states.

This suggests that experiencing is not believing, but one might still claim that both states have the same representational content. That claim has also been denied. For the conditions needed for thinking something may be different from the conditions for having certain kinds of experience: it seems conceivable that we can have the same experiences as infant humans or as other animals, but they cannot share the same thoughts as us; our beliefs are expressible linguistically, and rest on sophisticated conceptual abilities which neither infants nor other animals need have. One may also claim that the character of experience is too rich to be encompassed by any one set of categories, or set of concepts that one can bring to bear on it. For these, and related reasons, some philosophers have claimed that the content of experience is different from that of thought or belief in not being purely conceptual: experience has a non-conceptual content as well (see CONTENT, NON-CONCEPTUAL).
